The wage gap is one of the most obvious and enduring examples of the continuing presence of sexism in American culture. Despite the passing of the Equal Pay Act in 1963, which outlawed sex discrimination regarding pay, the U.S. Census Bureau reported in 2005 that for every dollar that a man earns, a woman earns 77 cents. The same report demonstrated that women are 40% more likely to live in poverty than are men. The National Committee on Pay Equity, a coalition of legal, educational, professional, and civil rights organizations, explained in 2005 that women workers are concentrated in low-wage paying occupations such as clerical, service, and sales positions; furthermore, as women workers become more prevalent in an occupational segment, income levels there decrease. A 2003 U.S. General Accounting Office report found that even when differences in work-related factors such as occupation, job tenure, and experience are accounted for, an unexplained 20% wage gap remains; this gap is attributable to discrimination. Intersections with racism mean that the wage gap for women of color is even more severe. In 2000, African American women’s average weekly wages were 64% of the wages of White men, while Latinas earned just 52% of that amount.

### *The Glass Ceiling*

One of the reasons that women workers tend to be found at the lower end of the pay scale is that corporate hierarchies do not advance women at the same rates as men, often promoting them only as far as the

so-called glass ceiling. First labeled as such by the *Wall Street Journal* in 1986, the U.S. Department of Labor convened the Glass Ceiling Commission in 1991 to study this phenomenon, defining it as an artificial, bias-related barrier that prevented qualified employees from advancing into management-level positions. In 1995, the Commission's final report documented the unquestionable presence of the glass ceiling with regard to women and people of color, finding that although women held more than 45% of the nation's jobs, 95% of senior managers were men. Furthermore, those women who were managers earned only 68% of what men made in similar positions. Ten years later, Catalyst, a research firm that tracks women's experiences in a wide range of workplaces reported that 50.3% of all professional and management positions and 1.4% of Fortune 500 CEOs were women. Six of these seven women were White; Andrea Jung, CEO of cosmetics maker Avon Products, is Asian American. In their 2005 study of corporate leaders titled "Men 'Take Charge' and Women 'Take Care,'" Catalyst researchers found that both men and women considered women to be more supportive but less leaderful than men and that men (but not women) believed that women are not good problem solvers.

Business is, of course, not the only workplace setting in which a glass ceiling is operational. In 2006, the *New York Times* reported that although law schools have been graduating equal numbers of men and women for roughly 2 decades, and although firms have been hiring graduates in comparable numbers, the percentage of women dwindles drastically in terms of who is promoted to the higher tiers of the firm: Approximately 17% of the partners at major law firms nationwide were women in 2005. Inadequate mentoring of women by predominantly male partners was cited as a factor, as was the fact that much of the networking and development opportunities that can advance a law career tend to take place in stereotypically male environments, such as football games or the golf course. Similarly, the American Association of Medical Colleges reported in 2001 that although 45% of medical students were women, there was an average of 21 women full professors per academic medical center, compared with 161 men at that rank. As for senior administrative positions, just 7.5% of medical department chairs nationwide were women. Women comprise one third of American journalists, according to Indiana University's 2003 American Journalist Survey, yet a 2001 study by Annenberg Public Policy Center found

that, among top media executives, women occupy only 13% of those positions.

### ***Sexual Harassment***

Another expression of sexism that can occur in a woman's place of work is sexual harassment. The U.S. Equal Employment Opportunity Commission (EEOC) describes sexual harassment as unwelcome sexual advances, requests for sexual favors, and other verbal or physical conduct of a sexual nature that explicitly or implicitly affects employment, interferes with work performance, or creates an intimidating, hostile, or offensive work environment. In 1979, feminist legal scholar Catharine MacKinnon pioneered the analysis of this issue in her book *The Sexual Harassment of Working Women*. Before MacKinnon's analysis was published, sexual harassment was often considered to be a normal, biologically based instance of "boys being boys"; MacKinnon was instrumental in explicating it as a discriminatory misuse of power within workplace culture. Today, many businesses actively educate employees about this form of discrimination, and the EEOC reports that 12,679 reports of sexual harassment were filed in 2005, as compared to a high of 15,889 in 1997.

### ***Women's Physical Health***

A nonsexist framework for understanding the prevalence of certain disorders among women locates them within a patriarchal context, bringing a focus to such issues as body image, eating disorders, sexual health, reproductive freedom, and the pathologizing of women's experiences through conventional mental health diagnostic practices. Throughout history, women's behaviors and feelings have been given various explanations and diagnostic labels by male-dominated society. Hippocrates warned that women who remained virgins for longer than was appropriate would find that their menstrual periods brought on visions, murderous rage, and a longing for death; women whose behavior did not conform to conventional expectations were hunted as witches for centuries. In the 19th century, medical textbooks portrayed women as the puppets of their ovaries and uterus, organs which were considered to be responsible for myriad mental and physical complaints as well as for the generally flighty nature and immature judgment seen as hallmarks of the feminine character.

In fact, the favorite diagnostic label for women of the late 19th century (which can still be heard today), *hysteria*, is derived from the Greek word for uterus.

Other forms of oppression also impact women's health, as evidenced by statistical data regarding the well-being of women of color. In 2002, the National Institute of Health released a report documenting the shorter life expectancies of women of color as compared with White women. Elevated risk factors were heart disease, cancer (especially African American women), diabetes (all women of color), cerebrovascular diseases (especially Native Americans), unintentional injuries, and HIV/AIDS (especially African American women). Eighty percent of all new cases of HIV/AIDS in women occurred among African American women and Latinas. Women of color were also at greater risk to give birth to low-birth-weight babies, to report unmet mental health needs, to be obese, and to be without health insurance. The cumulative impact of sexism and racism, compounded by the overrepresentation of both women and people of color among the nation's poor, leaves women of color the most vulnerable of all Americans in terms of basic health care.

Contraceptives are an important form of health care for women, enabling them to make basic decisions regarding their own fertility and sexual health. In December 2000, the EEOC moved to protect women from sexist deterrents to sexual health when it ruled that an employer's exclusion of contraceptives from its health insurance plan constituted impermissible sex discrimination. Protection of these rights has not always been consistent, however; in 2005, the Center for Reproductive Rights sued the U.S. Food and Drug Administration for violating its own procedures and statutes as it failed to approve the emergency contraceptive product Plan B for over-the-counter status. Emergency contraception, also known as "the morning after pill," reduces the risk of pregnancy when it is taken within 72 hours of unprotected intercourse. As of 2006, the federal government completed 3 years of its delay in providing a ruling on the distribution of Plan B. In a 2006 statement titled "The War on Women," Planned Parenthood explained its view that restricted access to contraceptives, the funding of medically unsound abstinence-only sex education programs, and the resulting reduction in access to family planning represented critical human rights violations regarding the health and empowerment of women.

In 1973, the Supreme Court established constitutional protection of a woman's right to choose

abortion in the well-known case *Roe v. Wade*. This ruling was in accord with advocates of women's rights and nonsexist reforms of women's health care, who pointed out that preventing a woman from exercising fundamental freedoms regarding her own body, including the rights to regulate fertility and terminate an unwanted or dangerous pregnancy, constituted a particularly overt demonstration of gender discrimination. Simultaneously, this ruling inspired the growth of the anti-reproductive rights movement, and the National Organization for Women estimates that the backlash to *Roe v. Wade* began in earnest when the Supreme Court upheld a Connecticut ban on public funding for abortion in 1977. Since 2000, the federal government has moved to limit women's reproductive freedom through such acts as the so-called Partial Birth Abortion Ban, which does not include an exception to preserve a woman's health. Most recently, the governor of the State of South Dakota signed a bill banning all abortions outright except in cases where the woman would otherwise die; survivors of rape or incest or women whose health or fertility were at risk were not protected. The citizens of South Dakota subsequently rejected the bill by a margin of 55% to 45%.

### ***Women's Emotional Health***

Feminist analysis has examined the ways that conventional psychological theory and psychopathological nomenclature are themselves derived from patriarchal constructions of femininity. Hope Landrine's work demonstrated that stereotypical assumptions about women's behavior form the basis for such personality disorders (PDs) as histrionic PD and dependent PD. In *Women and Madness*, Phyllis Chesler elaborated on this issue, explaining the double bind that women are placed in as a result: While both men and women who show these personality characteristics are considered ill, women will also be labeled as deviant if they *fail* to enact them to some degree. Along these lines, feminist psychologist and scholar Laura Brown has suggested that conceptions of mental illness derived from dominant culture norms have limited utility for understanding the difficulties experienced by members of subordinated groups, many of which might be more properly understood as "oppression artifact disorders."

Working as they do from gender-biased representations of mental health and disorder, it is not surprising that counselors' attitudes toward women clients can

be compromised by sexist stereotyping. Beginning with the work of I. K. Broverman in the 1970s, findings have demonstrated that clinicians have different standards and conceptions regarding the mental health of men and women, with typical adult women conceptualized as having characteristics incompatible with mentally healthy functioning more frequently than are typical adult men. Based on these analyses, feminist psychologists began in the 1960s to describe the ways that traditional approaches to psychotherapeutic practice were misapplied, and even oppressive, with regard to women clients. Women's experiences of living in connection to others were often pathologized by therapists schooled in the patriarchal belief that autonomy should represent the pinnacle of emotional development, and the power-over configuration of the conventional psychodynamic therapist–client dyad was shown to reproduce the subordinate position that women occupied in the larger society. Feminist counseling approaches were conceptualized to affirm the lived experiences of women, to encompass the oppression-related components of women's stories and struggles, and to facilitate empowerment within a collaborative working relationship. An example of one such approach is relational-cultural therapy, which originated with the work of Jean Baker Miller and continues to be elaborated by psychologists at Wellesley College's Stone Center. Taking women's experiences at the crossroads of multiple oppressions as a point of departure, relational-cultural theory posits that psychological connection, rather than separation, is most crucial to understanding optimal human growth and development. The counseling relationship, then, is reframed with an emphasis on mutuality, empathic connection, and power sharing.

### **Cultural Representations of Women**

Representations of women in the media, particularly in advertising, have been analyzed over the years for their sexist depictions of women. Contemporary popular culture features women in a much wider variety of roles than were seen decades ago, yet whether they are doctors, lawyers, housewives, detectives, or psychics, women are still portrayed as overwhelmingly young, thin, beautiful, White, and dressed in the latest fashions. Patriarchal emphasis on women as objects of men's attentions, combined with the bottom-line motivations of the billion-dollar fashion and cosmetics industries, compels women to conform to

this culturally prescribed feminine ideal; as Susan Brownmiller explained in her 1984 book *Femininity*, to fall short in one's achievement of "the feminine difference" is to appear not to care about men, to risk the loss of their attention and approval, and to thereby relinquish one's core identity as defined within a patriarchal context.

Culturally constructed ideals of female beauty are frequently used to sell products featured in advertisements, and the toxic environment that this creates for women has been explored by media analysts such as Jean Kilbourne, author of *Deadly Persuasion: Why Women and Girls Must Fight the Addictive Power of Advertising*. Commercial images are increasingly more unrealistic, thanks to the development of digital photo-enhancement technology, and frequently depict thin, young, partially nude White women posed in sensual or sexual contexts. Older women, when depicted at all, are also presented in ways that reinforce the predominant commercial image: Most often they appear uncommonly youthful and are selling cosmetics, drugs, or surgeries promising to offer the same. Women of color and larger-sized women are, for the most part, invisible or relegated to specific niche markets. Such images create anxiety for women, regarding the appearance of their own normal, healthy bodies, and are a factor in the development of eating disorders, body dysmorphic syndromes, and the abuse of diet regimes and medications. With regard to women of color in particular, these images simultaneously enforce a White beauty ideal, paving the way for sales of hair straighteners, skin bleaches, and colored contact lenses.

Problems with body image and eating illustrate the relationship between cultural messages to women regarding their appearance and the ways that women care for their own bodies. Susie Orbach, author of the 1978 book *Fat Is a Feminist Issue*, explored the idea that, in a patriarchal context, weight gain can be seen as a form of rebellion against these often-impossible standards. In 1991, Naomi Wolf elaborated on this theme in *The Beauty Myth*, relating the cultural obsession with smaller-sized women to a patriarchal enforcement of their diminished status in society. Pointing to a cultural backlash against feminism, Wolf demonstrated that the more equity women have achieved, the more harshly cultural prescriptions for beauty have constrained them, as seen in the upsurge in anorexia, bulimia, cosmetic surgery, and diet pills and products.

## Violence Against Women

Patriarchal oppression has life-threatening consequences when it is expressed through violence against women. Many women have experienced everyday forms of violence, such as sexual comments on the street, acquaintance rape, obscene phone calls, or sexual harassment at work, aggressions that society often sanctions by blaming the woman herself: She “asked for it,” her attire was too provocative, she has no sense of humor, and so forth. Unfortunately, significant numbers of women also face more serious threats to their safety and health. The National Organization for Women reported in 2005 that one in six women will experience rape. Half of women who report rape are under the age of 18, and 22% are under the age of 12. Estimates are that domestic violence affects from 2 to 4 million women each year, with at least 170,000 of those attacks being serious enough to require emergency room care. According to the United Nations Commission on Human Rights, pornography also represents a form of violence against women, in that it legitimizes the degradation and maltreatment of women and asserts their subordinate function with regard to men.

## Internalized Oppression

Sexism, like other forms of oppression, is learned by both dominant and subordinate members of society, with the result that women themselves, intentionally or not, participate in the enforcement of oppressive restrictions in their own lives and on other women. When women take oppressive, patriarchal definitions of femininity into the deepest levels of their own identity, it is called *internalized oppression*. In other words, when women believe in their own inadequacy, when they feel that they cannot be seen without makeup on their faces, when their speech is characterized by expressions of tentativeness and uncertainty, when they attempt to conceal their intelligence, when they disparage other women who speak up, when they wear comfortable clothing, or when they otherwise defy conventional stereotypes, they are revealing the extent to which they have internalized their own oppression. In her 2003 book *Women's Inhumanity to Women*, Phyllis Chesler explored the ways that women wound themselves and each other by gossiping and scapegoating other women, allowing their relationships with women to be competitive and transient as they prioritize obtaining the attentions of men. Women's reluctance to associate themselves with movements of women can be seen as part of this

trend, reminiscent of the old Groucho Marx line, “I wouldn't join any club that would have me as a member.” bell hooks has described the paradoxical phenomenon that is created by this reluctance: modern women who have benefited throughout their lives from feminist-generated social reforms yet go to great lengths to insist that they are not feminists.

Women of color and queer women internalize double and triple doses of oppression. In her book *Homophobia: A Weapon of Sexism*, Suzanne Pharr elucidated the linkages between homophobia, heterosexism, and sexism. Attacks and discrimination against lesbians and gay men serve to enforce the traditional heterosexual power structure, in that adults who break ranks by defying conventional sex role behaviors—women who are not dependent on men, men who do not structure their identities around difference from and dominance of women—are ostracized. To identify as a lesbian, then, is to be stigmatized as the ultimate outsider within a patriarchal context. In her book *Sister Outsider*, Audre Lorde explored the anger, suffering, and self-rejection that racism, heterosexism, and patriarchy create, dividing women of color from themselves and each other.

## Transcending Sexism

Feminists are sometimes speciously dismissed as advocating something like a reversal of dominant-subordinate sex roles as the alternative to sexism. In fact, a world beyond sexism is envisioned as one in which both men and women are free to live, learn, work, and love without the confinement, the posturing, and the damage imposed by patriarchal sex role requirements. As bell hooks explained in her book of the same title, feminism is for everybody.

## SOCIAL IDENTITY THEORY

---

Originally developed by Henri Tajfel and John Turner to understand the psychological bases of intergroup discrimination, social identity theory seeks to explain the psychological and social bases for intergroup behavior and has more recently been used to also understand intragroup processes. Social identity theory can be used in the contexts of multicultural counseling, research, and practice to understand the processes by which individuals develop and maintain social identities and groups. The theory includes three core elements: social categorization, social identification, and social comparison. Social identity theory proposes that individuals engage in a natural process of categorizing their social world into “us” and “them.” Individuals strive for a positive self-concept and maintain and enhance their self-esteem through their memberships in social groups. Individuals derive positive valuation from their ingroup (i.e., members of the group to which they belong) through engaging in social comparison of their group with other groups. To enhance their self-concept, individuals view their

social groups as unique and of higher status than other groups.

### Social Categorization

Individuals naturally categorize their social environment into those in their ingroup and those in outgroups. Tajfel and Turner suggest that this simple categorization is sufficient to trigger ingroup favoritism and outgroup discrimination. That is to say, individuals need only be aware that an outgroup (i.e., those with whom they do not share group membership) exists for them to engage in intergroup competition with those whom they perceive are part of their outgroup.

Individuals engage in categorization because it helps to simplify the social environment. Therefore, individuals will categorize people according to how similar and different they are to each other. Furthermore, individuals will accentuate these perceived differences in a stereotyped fashion, viewing people as more similar to or more different from them than they actually are.

### Social Identity

Individuals are thought to have multiple levels of identity that define who they are. On the most basic level, individuals define themselves according to individual personality traits and interpersonal relationships, and this is referred to as *personal identity*. Through social categorization, individuals also understand themselves as members of social groups and derive social identity from these group memberships. Specifically, social identity includes those aspects of a person's self-concept that are based on their perceived membership in social groups (e.g., Black, Catholic, university student).

### Social Comparison and Positive Distinctiveness

To have a positive self-concept and social identity, individuals engage in social comparison with other groups and view themselves as better than and different from members of other groups (i.e., with positive distinctiveness). The dimensions along which individuals of one group differentiate themselves from other groups depend on the social context. For example, race is a salient attribute with which ingroup and outgroup members are defined in the United States, whereas it may not be a relevant attribute in other countries. For

social comparison to take place, outgroups must be seen as similar enough to the ingroup to make social distinctions relevant, and all groups must agree that the attribute of distinction is of importance.

It has been argued that regarding one's ingroup with positive distinctiveness is essentially a form of intergroup competition because the goal of such a comparison is to assert the group's superiority over an outgroup. As such, social identity theory has been widely used to understand intergroup discrimination and conflict, as well as social changes that involve an individual's desire for mobility into a more positively regarded social group or a group's efforts to assert positive distinctiveness.

### Implications

Social identity theory aids in our understanding of intergroup social phenomena, such as stereotyping and discrimination, as well as intragroup social phenomena, such as differentiation of members within the group and within-group effects on individual attitude change.

#### *Intergroup Processes*

*Stereotypes and Discrimination.* When social identity is salient, an individual perceives his or her group to be normative and holds attitudes and behaviors consistent with perceived group norms. Self-enhancement results in individuals viewing their group favorably while holding negative stereotypes about the outgroup. Intergroup behavior can thus be understood as the collective action of individuals of an ingroup who behave similarly and treat outgroup members similarly, viewing them as stereotypically homogeneous.

Social groups organize into status hierarchies as a result of social comparison. According to social identity theory, when individuals do not derive a positive social identity from a particular group membership, they will strive to leave this group and/or act to make their group more positively distinct.

Individuals who strive for upward social mobility try to dissociate from members of the ingroup that they perceive as lower in the status hierarchy and display preferences for members of a higher-status group. An example of this phenomenon is internalized racial oppression, involving self-hate among racial minorities and their desire to emulate mainstream

White Americans. Mobility out of a lower-status group is considered an individual rather than a group endeavor, and while possibly changing the status of an individual, such individual mobility does not change the status of the groups.

Rather than attempting to leave their existing groups, some members of lower-status groups may instead try to make their group more positively distinct. They can do this by redefining how their group is being compared with others. For example, lower-status groups may attempt to emphasize another dimension for social comparison, one that casts a more positive light on them. Lower-status groups may also change the values of attributes assigned to their group from negative to positive. For example, whereas being African American was perceived to be negative, the Black nationalism movement in the 1960s and 1970s, proclaiming that "Black is beautiful," redefined being Black as positive. In addition, lower-status groups may select a different outgroup as a comparative frame of reference. This usually involves selecting a comparison group that is perceived to be of lower status than the group. These processes by which members of lower-status groups attempt to make their group more positively distinct are collective actions that attempt to change the status of the group as a whole.

Another way that an ingroup may assert their positive distinctiveness is by attempting to change the status position of their group along the valued dimension of comparison. For example, the civil rights movement was an attempt by minorities to change their status position in the United States through fighting for more rights. The result of social competition changes the status hierarchy as a whole. When competition occurs over scarce resources, social competition will lead to conflict between higher-status groups, who wish to retain their resources and social position, and lower-status groups.

#### *Intragroup Processes*

More recently, social identity theory has been applied to better understand how individuals organize themselves within groups. When individuals define themselves with a social identity, they construct and conform to the ingroup norms. However, few groups exist where all members are entirely homogeneous. According to social identity theory, differentiation among members of an ingroup may be allowed, with the nature of such differentiation dependent on the social context in which

group norms are agreed. Members of a group may agree that heterogeneous roles among members are allowed or even necessary for the group to enhance its positive distinctiveness. Individuals are allowed a level of optimal distinctiveness, or the freedom to balance the desire to be part of a group while maintaining individuality, so long as there remains a greater perceived difference between, rather than within, groups. For example, a basketball team comprises players who all identify as members of the same team, but each player contributes to help the team win games.

Attitude change is internalized by individuals through their self-categorization as group members. For example, Jim Sidanius and his colleagues have found that ethnic minority college students' membership in ethnic organizations increases not only their sense of ethnic identity but also their perceptions of discrimination.

Social identity theory informs our broad understanding of the complex social processes through which individuals interact with others as individuals and as group members. This perspective is shaped entirely by the sociocultural context in which individuals and groups reside.

## SOCIAL JUSTICE

Social justice refers to the promotion of full and equal participation of all individuals and groups, allowing their needs to be met equally. Most societies around the world have fallen short of creating conditions of social justice. This is evidenced by the existence of marginalization in many societies, as evidenced by the fact that many groups do not have full participation or share equal power in society because of race, ethnicity, age, socioeconomic status, religion, disability, or sexual orientation. Because inequities exist based on these cultural differences, societies that strive for social justice often have attempted to identify and rectify the existence of oppressive structural barriers embedded in the social, economic, and political systems. Historical examples within the United States are the women's suffrage movement that led to the federal right for women to vote in 1920 and the civil rights movement in the 1960s, which was aimed at abolishing racial discrimination against African Americans.

The negative psychological effects of social injustice are numerous and include the development of symptoms such as depression and anxiety. Within the field of psychology, it has been argued that the reality of oppression and social injustices must be incorporated into the treatment plans of individuals who are members of marginalized groups (e.g., women, people of color). A failure to acknowledge the adverse effects of social injustice on individuals' mental health and functioning can be problematic for many reasons. For example, a recent immigrant who is having difficulty finding a job may benefit from having a counselor with whom to process his or her frustrations, but therapeutic processing alone may not be sufficient in helping the client understand the full range of reasons he or she has had difficulty finding work. A counselor who is not aware of the potential of societal oppression might even attribute the client's difficulty in finding work solely to individual factors (e.g., an underlying personality issue), rather than the possibility that the client is also facing workplace discrimination. As a result, the client may end up feeling as misunderstood in therapy as he or she does in other facets of life.

Because the genesis of some mental health problems can include experiences of social injustice, it has been argued that mental health professionals should expand their roles beyond that of traditional counseling.

Although the counselor can provide a place to process emotions related to oppression, of equal importance is the counselor's role as an agent of social change. Rather than changing people only through individual empowerment, a social justice framework within the mental health field encourages counselors to change the contextual variables that contribute to social inequity and oppression. Numerous scholars have suggested that client advocacy and public policy work can be infused into the skills of counselors.

Advocating for social justice requires that mental health counselors become more knowledgeable about oppression and societal inequities and how they are experienced by individuals and groups. For example, a counselor may benefit from visiting the neighborhood in which a client resides so as to learn more about the client's everyday experience. When counselors learn more about their clients' communities, they are better able to assist clients in accessing their indigenous support networks, such as religious leaders, community leaders, friendship networks, and family. Counselors must also personally reflect on issues of oppression and privilege in their own lives. An important part of being a social justice-oriented counselor is to critically examine one's experience as an oppressor, the oppressed, or both. To think critically about these experiences may influence the ways one conceptualizes and interacts with clients.

In addition to increasing knowledge of oppressive forces and gaining self-awareness regarding power and privilege, it is important that counselors strive to actively engage in the work of social justice on behalf of their clients. For example, counselors can implement and evaluate both remedial and preventive mental health intervention programs to assist marginalized populations. Preventive mental health interventions can serve as a unique way to effect change within a community. Rather than waiting until a problem occurs, prevention programs provide the possibility of protecting their stakeholders from the negative outcomes of social inequity. Counselors can become more involved in community organizations that confront social injustice as a way to not only assist the community but also extend the scope of their reach beyond individual client. Thus, a commitment to social justice requires more than becoming aware of inequity; it requires a commitment to working to end inequity.

Professionals in the field of counseling have unique insight into the detrimental effects of oppression and social injustice on individual health and well-being.

It is incumbent upon such professionals to advocate for marginalized groups to help alleviate oppression. In addition to implementing outreach and prevention programs that are aimed to alleviate the detrimental effects of oppression, counselors can also play an important role as advocates for political policies that seek to end the injustices that plague marginalized communities. This has implications for training mental health professionals to become competent with members of historically marginalized groups.

Educators must not only train counseling students to develop multicultural competence (i.e., the ability to work effectively with diverse and marginalized populations) but also encourage students to act individually and in groups to become agents of social change. In addition to teaching these important skills and encouraging discussions of political and social issues, counselor educators should encourage trainees to get involved in out-of-class activities on campus and in the surrounding community. This could include the addition of real-world experiences as a component of courses that focus on topics of oppression, prevention, outreach, and/or advocacy. Such real-world experiences might include facilitating students' creation of an action research project that examines social issues within the campus, or organizing and participating in a service project that benefits local underserved populations. Through such outreach and service activities, counseling students will develop a greater understanding of the diverse experience of others and be exposed to broader social issues.

In addition to infusing social justice teachings into counselor training programs, counselor educators must enact a combination of advocacy research and social action designed to support the oppressed rather than the powerful. Research aimed at social justice should focus, in particular, on how institutions serve to promote or sometimes prevent social changes and on how individuals and groups can overcome the consequences of an oppressive system. In addition, action-oriented research would assess the need for, or impact of, social policies within marginalized groups and communities (i.e., needs assessments or outcome studies). The delivery of research findings to policy makers through direct presentations to community members and leaders who can get involved at the policy level is imperative. A link between social justice research and its intended beneficiaries must be maintained for the

field of counseling to continue to serve as an active agent of social justice.

## SOCIETY FOR THE PSYCHOLOGICAL STUDY OF ETHNIC MINORITY ISSUES

---

The American Psychological Association (APA) is organized with divisions that focus on specialty and interest areas within psychology. As one of the 56 divisions of APA to date, the Society for the Psychological Study of Ethnic Minority Issues (also known as Division 45) has its own governance structure elected by its members.

The Society for the Psychological Study of Ethnic Minority Issues serves as a means to promote the development of knowledge and understanding of ethnic minority psychology; the application of psychological principles specific to ethnic minorities; consideration of how social concerns impact ethnic minority populations; and the incorporation of the importance of cultural diversity in society. The purpose of this organization, as noted in the Division 45 bylaws, is to advance the contributions of psychology as a discipline in the understanding of issues related to people of

color through research, including the development of appropriate research paradigms; to promote the education and training of psychologists in matters regarding people of color, including the special issues relevant to the service delivery issues relevant to ethnic minority populations; and to inform the general public of research, education and training, and service delivery issues relevant to ethnic minority populations.

The formation of Division 45 can be traced to a long history of efforts by many individuals and organizations through the years, and a good account of this history can be found in an article by Lillian Comas Diaz in the division's journal, *Cultural Diversity & Ethnic Minority Psychology*. In addition, a list of Division 45 founders is provided on Division 45's Web site. The Council of Representatives of APA voted to establish Division 45 at the August 1986 annual APA meeting. An interim president and executive committee were selected to set up the organization and establish bylaws and procedures. Elections were held in 1987, and the first elected executive committee of Division 45 was formed. Division members elect representatives to the APA Council of Representatives, which is the governing body of the APA, and set policies and direction for the organizations and the field of ethnic minority psychology. Division 45 also has provided leadership in generating many policy changes within APA, as well as in contributing to the knowledge base of the field of psychology. In particular, significant inroads have been made to effect the representation of ethnic minority psychologists within the governance structure of the APA.

Division 45's journal, *Cultural Diversity & Ethnic Minority Psychology*, is regarded as one of the top APA journals in terms of utilization rate, hit rates on computerized searches, and subscriptions. The division's newsletter, *Focus*, is published twice a year and provides information about Division 45's activities and provides articles of interest to the membership of the division. Members of Division 45 have been very active in many other APA divisions and have advocated for the inclusion of multicultural issues within the field of psychology at large. This advocacy fostered the development of the *APA Multicultural Guidelines*, which were approved by the APA Council of Representatives in 2002. This document described cultural competencies for psychologists and the expected approaches for incorporating ethnic minority issues in research, teaching, psychology training, and practice. The *APA Multicultural Guidelines* represent a

central guiding source for evaluating psychologists for licensing, ethical practices, training and education, and professional advancement in colleges and universities.

Division 45 also has collaborated on various other projects with APA divisions to enhance cultural diversity training and to bring resources to a broader audience, such as state psychological associations, practitioners via online continuing education training, and conferences, to examine various issues and evidence-based practices for ethnic minority groups. For example, several APA divisions have collaborated and cosponsored a biannual Multicultural Summit conference that focuses on ways to advance the field of psychology through multiculturally sensitive and competent efforts. Other such conferences have emerged or are being planned with similar collaborations on topics such as the impact of immigration, the effect of violence in diverse communities, and evidence-based practices with ethnic minorities.

## SOCIETY OF INDIAN PSYCHOLOGISTS

---

The Society of Indian Psychologists (SIP) is a formal professional organization of American Indian, Alaskan Native, and non-Native psychologists, as well as other affiliated professionals, whose purpose is to promote and improve the psychological health and well-being of the indigenous peoples of the Americas. Additionally, SIP advocates for the development and application of culturally competent and

relevant psychological theory, research, education, and clinical practice with American Indian and Alaskan Native peoples.

Through biannual meetings, Internet listservs, and other venues, the society provides a forum for professionals who share these collective concerns to consult with one another. SIP also serves as a network for American Indian and Alaskan Native professionals. This network provides opportunities for professional development, advisement, mentorship, and sharing of knowledge, experience, and skills for American Indian and Alaskan Native psychological professionals and others who work with indigenous communities.

### Beginnings

The precursor to SIP was an informal group of newsletter subscribers, persons interested in sharing information about psychological services then available in indigenous communities. The newsletter, called *Network of Indian Psychologists*, was founded in 1970 and solely administered by Carolyn Attneave (Delaware/Lenni Lenape), an internationally renowned American Indian psychologist. Five years later, SIP was formally established as a professional organization for American Indian and Alaskan Native psychologists. Today, with a membership of more than 300 professionals, SIP continues to honor Attneave's revolutionary work through sponsoring a memorial scholarship fund in her name.

### Policy Making

SIP is one of five national ethnic minority psychological associations; other such organizations include the Association of Black Psychologists, Asian American Psychological Association, National Latina/o Psychological Association, and the Society for the Psychological Study of Ethnic Minority Issues (Division 45) of the American Psychological Association. Together, these organizations constitute the Council of National Psychological Associations for the Advancement of Ethnic Minority Interests.

In 1999, SIP proposed a resolution that supported the retirement of all Indian mascots, personalities, images, and other symbols in use within schools, colleges, universities, and athletic teams in the United States. In 2005, the highest governing body of the American Psychological Association, the Council of Representatives, adopted a similar resolution that

recommended immediate retirement of American Indian mascots within educational institutions, athletic teams, and organizations. Both resolutions were based on concerns about the ethical practice of psychology within these contexts as well as psychological research that had demonstrated harmful and negative effects of the use of Indian mascots and other symbols on American Indian children, communities, and students.

## SOCIOECONOMIC STATUS

---

Socioeconomic status (SES) typically refers to a person's position and esteem in society based on economic and other resources. The most commonly cited indicators of SES are income, occupation, and education. In social science research, SES is often used interchangeably with the term *social class*. However, some would argue that these are different terms and that social class is determined both by the quantifiable amount of resources someone has and their relative standing in relation to others. For example, the terms

*lower class*, *middle class*, and *upper class* can be thought of as income demarcations and are often used as such in census data, but others look at these terms as descriptors of job prestige (e.g., both a college professor and a lawyer may fit into the “upper class” category though their incomes differ greatly). N. Krieger, D. R. Williams, and N. E. Moss, in their paper on measuring social class in public health research, stated that “socioeconomic position” consists of both actual resources and status (i.e., qualities related to prestige and rank). The confounding between the terms *SES* and *social class* reflects the lack of clarity of these concepts in society due to the “myth of the classless society,” which is the idea that ability and effort alone are responsible for one's class standing. Oppression by those with material and power and privilege also contributes to the confusion of these terms. This entry focuses on SES but integrates social class concepts as they are relevant to counseling psychology.

## SES Indicators and Disparities

### Income and Wealth

*Income* is defined as money received (e.g., from wages, interest, child support, Temporary Assistance to Needy Families), whereas *wealth* consists of assets accumulated. Another way to define wealth is net worth, or assets (e.g., home ownership, stocks, cars, leftover income after expenses) minus debts. Typically, when talking about SES in the United States, the media focus on income. However, wealth statistics paint a more accurate picture of SES and inequality. In addition, income cutoffs for federal programs such as food stamps do not accurately portray the amount of money actually needed for U.S. families to meet basic needs.

According to the U.S. Census Bureau, the median income of families in the United States in 2004 was \$44,389. There are significant income disparities based on race. In 2004, the median household income was \$48,977 for non-Hispanic Whites, \$30,134 for Blacks, \$57,518 for Asians, and \$34,241 for Hispanics. These figures are estimates and often omit working undocumented immigrants and intergroup differences, such as the status of Southeast Asian refugees.

There are also disparities in income between men and women. The median income for men with earnings in 2004 was \$40,798, and for women with

earnings it was \$31,223. According to this estimate, women are making almost 77 cents on the dollar compared with men. Other estimates claim that the pay gap is decreasing, and women are making about 80 cents for every dollar of men's earnings. However, part of this narrowing is due to the fall of wages for working-class men rather than increases in wages for women.

In 2004, 12.7% of the U.S. population lived below the poverty line. That year, the Department of Health and Human Services defined the poverty threshold as an income of \$18,850 for a family of four. However, many economists and social scientists question the formula used to calculate this figure. The threshold is calculated using a formula that was developed in the 1960s, based on the cost of food for a family multiplied by three. This formula fails to incorporate rising housing and healthcare costs, not to mention the need for child care in most American families. Several economists have proposed new formulas for calculating the income that families need to meet their basic needs, and the results of these formulas suggest that families in the United States need an average of 2 times the federal poverty threshold to simply survive. In some regions of the country, the difference is even greater.

Continuing to use the Department of Health and Human Services definition of poverty, glaring differences based on race are apparent. The poverty rate (percentage of the population living under the federal poverty threshold) in 2004 was 8.6% for non-Hispanic Whites, 24.7% for Blacks, 9.8% for Asians, and 21.9% for Hispanics. Two-year average poverty rates (2003–2004) were calculated for American Indians/Alaska Natives and Native Hawaiian/Pacific Islanders, respectively: 24.4% and 12.9%. There are also disparities based on citizenship status. The poverty rate for U.S.-born citizens was 12.1%, compared with 9.8% for foreign-born naturalized citizens and 21.6% for noncitizens. Female-headed households are much more likely to experience poverty. The poverty rate for female households with no husband present was 28.4%. For male households with no wife present it was 13.5%, and for married couple households it was 5.5%.

Wealth disparities are even more staggering. The median net worth (i.e., assets minus debts) for White households in 2001 was \$121,000. For Black households, the median was \$19,000, and for Latino/a households the median was \$11,500. Even as the gap in income between races decreases very slowly, wealth disparities have stayed the same or increased.

Some economists and social scientists, such as Chuck Collins and Felice Yeskel, the authors of *Economic Apartheid in America* with United for a Fair Economy and Class Action, argue that inequality is a critical social problem even if the standard of living has improved for Americans overall. They discuss inequality between racial and ethnic groups, men and women, and wealthy and poor (and, increasingly, between wealthy and middle-income people). Salaries of chief executive officers (CEOs) and other executives have increased exponentially, while workers' wages are stagnant or even decreasing. In addition, CEOs' salaries are positively correlated with downsizing, so as more and more working and middle-income people lose their jobs, the wealth of executives increases. In 2003, the average CEO made as much money as 301 workers. According to the U.S. Census Bureau in 2004, income for families in the top 5% of the population grew by 75% between 1979 and 2003, and for those in the middle 20%, income grew by only 15% during the same period. In 2001, 10% of the population owned 70% of all wealth, and 90% of the population owned 30% of all wealth. Collins and Yeskel reviewed several studies regarding inequality and public health and found that the regional gap between the rich and the poor predicts health better than poverty rates do. In the United States in particular, most working people are working longer hours and earning less; struggling to afford health insurance, higher education, and retirement; going into more debt to pay for everyday expenses; saving less; and working more temporary jobs with no security or benefits.

### Occupation

Occupation is another indicator of SES used in social science research. Some researchers simply distinguish between the employed and unemployed, and others use various job categorization schemes. Nancy Lynn Baker noted that the current terms for distinguishing between social classes (e.g., *working class*, *professional class*) are simply job descriptions and do not capture important distinctions between occupations, such as personal control and level of danger.

Occupations are sometimes grouped by income, but most schemes rely on categories based on prestige, skill, or education required. The U.S. Census groups occupations into 23 major groups, some of which are management; legal; education, training, and library; protective services; building and grounds;

cleaning and maintenance; sales and related; office and administrative support; construction and extraction; and transportation and material moving. According to the U.S. Department of Labor, in May 2005, the occupational group with the highest mean annual wage was management (\$88,450), and the occupational group with the lowest mean annual wage was food preparation and serving (\$17,840). However, understanding SES by these categories is not particularly meaningful, as management occupations include, for example, CEOs and social and community service managers, and food preparation and service-related occupations include both chefs and dishwashers. In both cases, these occupations differ greatly in terms of income, education required, prestige, and personal control over one's workday. Prestige and power are associated with such categories, as captured by the Occupation Score of the Hollingshead Index of Social Position. The original Hollingshead Two-Factor Index grouped occupations from highest prestige (which could be called business management and professionals) to lowest prestige (unskilled employees). Industrialized nations seem to have similar conceptions of occupational prestige. Michael Argyle reviewed studies of occupational prestige across various countries and found that professionals are usually held in highest esteem, whereas unskilled service workers, farmers, and farm laborers are usually regarded in lowest esteem.

In his book *The Working Class Majority: America's Best Kept Secret*, economist Michael Zweig defined social class in terms of the power workers have in different occupations. He discussed three types of power important in determining one's social class: economic power (based on earnings and wealth, and power over the means of production, including other workers), political power (the power to influence policy), and cultural power (power over the processing of information, such as the media and education). Though someone could have one type of power and not another, all three types generally reinforce one another. He divided occupations into three major classes based on the amount of power each class has: the capitalist class (which includes the ruling class), the middle class, and the working class.

The capitalist class consists of business owners, particularly owners of corporations or "big businesses." Many small business owners fit into Zweig's definition of the middle class. The distinction is that members of the capitalist class do not come into much

contact with workers or the process of production, though they have great control over the workforce through middle management. The ruling class consists of a small percentage of the capitalist class who serve on the boards of several corporations, affording them access to political and cultural leaders. Zweig defines the middle class as small business owners; supervisors and managers; and professionals, such as doctors, professors, and computer programmers. He described the middle class as caught between the competing interests of the working and capitalist classes: On the one hand, they have an interest in maintaining their privileges by limiting the power of working-class people, but on the other, they are losing control over their jobs (e.g., designing curricula, HMO policies) to the capitalist class. The working class is the largest class according to Zweig's analysis (about 60% of the U.S. workforce) and is quite diverse. Working-class people are those with the least amount of power and control in their occupations. In the U.S. Census categories, they are typically found in sales, administrative support services, production, and technical occupations. Zweig estimates that 75% of the unemployed are working-class people actively looking for jobs.

## Education

Education is often used as a descriptive indicator of SES, distinguishing between those who have not completed high school, those who have completed high school or have obtained a general equivalency diploma, those who have 2-year or vocational degrees, and so on. Education is considered a major vehicle of upward social mobility, as higher education is tied to occupations with higher incomes and prestige. However, the education and income of one's family of origin are highly predictive of future educational opportunities. Income, occupation, and education appear to be intertwined and mutually reinforcing. In the United States in 2003, the median annual income for non-high school graduates was \$15,610. This figure was \$30,936 for those with associate degrees, \$40,588 for those with bachelor's degrees, \$51,116 for those with master's degrees, \$70,985 for those with doctorate degrees, and \$81,833 for those with professional degrees.

In the United States, there are stark racial/ethnic disparities in education. According to the U.S. Census Bureau in 2004, 89.2% of non-Hispanic Whites ages 18 and older had a high school diploma or more,

compared with 79.5% of Blacks, 86.8% of Asians, and 58.9% of Hispanics. More striking disparities are found in higher education. Twenty-eight percent (28.2%) of non-Hispanic Whites age 18 and older had a bachelor's degree or higher, compared with 15.6% of Blacks, 45.6% of Asians, and only 10.3% of Hispanics. Note that data were not available for American Indians, Alaska Natives, or Native Hawaiians and other Pacific Islanders, who typically fare worse than other groups on SES indicators.

### ***Classification Schemes Based on Prestige***

Two of the most popular classification schemes for SES are August B. Hollingshead's Index of Social Status and Otis Dudley Duncan's Socioeconomic Index. Both of these methods rank occupational categories based on prestige. These methods are based on census data from 1970 and 1950, respectively, and are thus outdated. The Hollingshead Index combines education, occupation, gender, and marital status into one social status score. The Duncan Socioeconomic Index classifies occupational prestige based on the income of, and education required for, the occupation. Another classification method is the Nam-Powers Socioeconomic Status Score, which uses a definition of occupational status based on median income and education of those employed in that occupation, combined with educational level and family income. Problems with these measures include few studies on validity and reliability, the combination of highly intercorrelated SES indicators into one measure, and equating socioeconomic resources with prestige.

## **SES and Health**

### ***SES and Physical Health***

There is a clear relationship between SES and health, as indicated by studies that have found evidence of a gradient where low SES is correlated with most (but not all) diseases, and the likelihood of contracting or experiencing disease decreases as SES increases. Relationships between various socioeconomic indicators and physical diseases have been found, including cardiovascular disease, hypertension, and certain types of cancer. Level of education alone has been cited as a predictor of mortality and morbidity in the United States and other countries.

SES is highly correlated with physical health for various reasons. Access to health care, safe workplace conditions, and supportive social networks contribute to the health of those with higher SES. In addition, lower SES is associated with a greater likelihood to engage in risky behaviors, such as smoking and alcohol consumption. Individuals coping with the stress of a low SES environment are also less likely to engage in healthy behaviors such as exercise. The physical environment of low SES neighborhoods can also directly impact health. Impoverished neighborhoods are often exposed to pathogens, carcinogens, and environmental hazards. People in poor communities are also more likely to be exposed to, or experience, violence and may have less social support than people living in higher SES communities.

Nancy E. Adler, Elissa S. Epel, Grace Castellazzo, and Jeannette R. Ickovics conducted a study in which they found strong correlations between subjective SES and health, by asking 157 healthy White women to rank their social status on a 10-rung ladder. Significant negative correlations were found between subjective SES indicators of poor health (e.g., body mass index). The researchers also measured psychological health and found significant negative correlations between subjective SES and negative affectivity, chronic stress, subjective stress, pessimism, and passive coping. Significant positive correlations were found between subjective SES and control over life and active coping. This is one of several studies demonstrating relationships between SES and both physical and mental health.

### ***SES and Mental Health***

People living in low SES communities face multiple stressors and often do not have the material or social resources to cope with the resulting stress. Aside from severe financial crises that poor families face (hunger, threats of eviction, etc.), they face more hassles in their daily living than do families in higher SES communities. Those of higher SES have more access to high-quality housing, shops, banks, health care, and transportation. These resources alone can be buffers against stress.

Citing national epidemiological studies, Yan Yu and David R. Williams stated that in 1994, individuals who did not complete high school were almost two times more likely to be diagnosed with a major affective disorder than individuals who had a college education or more. In addition, people of low SES were almost

2 times more likely to suffer from a substance abuse disorder than people in the highest SES group. Though these disparities may be the result of the stressors described above, it is possible that classism, racism, and other forms of oppression affect rates of diagnosis in people of low SES. Considering the SES disparities between races in the United States, it is clear that racial/ethnic minorities are more likely to be diagnosed with a psychiatric illness than are White individuals.

Depression has been linked consistently with poverty in adults and children. According to Deborah Belle and Joanne Doucet, adults in poverty are at double the risk for experiencing a new episode of major depression than are other adults. This compounds children's risk for depression and other mental health problems. Poor household economic conditions increase the risk for childhood depression and the poor physical health correlates of depression. Other risk factors for childhood depression that are linked to SES are living in a single-parent home, parental unemployment, and low educational attainment by parents. A recent meta-analysis by Vincent Lorant and colleagues concluded that there is a moderate to strong relationship between SES and depression, and this is especially true for persistent depression.

## SES and Counseling

### *Classism and Counseling Psychology*

Bernice Lott and Laura Smith have called attention to the classism that exists in psychological research and practice. Classism, like other forms of oppression, results from those with unearned class privilege exerting their power over others. Lott discussed notions of class superiority and inferiority that result in psychologists and others distancing themselves from poor people through cognitive means such as stereotyping; exclusion of low SES individuals from institutions such as education, housing, and politics; and interpersonal means such as blatant discrimination and invalidation.

Smith traced the history of psychotherapy's treatment of the poor, including the political backlash against community mental health centers and therapists' expectations of clients based on White middle-class norms. Current therapeutic models are most likely not addressing the needs of those from lower SES groups, as evidenced by higher treatment dropout rates. An example of an attitudinal barrier is counselors seeing their interventions as less significant

because poor clients are facing multiple stressors. As the multicultural counseling competencies have helped to address counselors' attitudes regarding race and ethnicity, identification of attitudinal barriers to working with low SES clients will begin to increase counselors' competence to work across socioeconomic groups.

### *The Social Class Worldview Model*

William M. Liu developed the Social Class Worldview Model (SCWM) to address the definitional problems surrounding class and SES and to analyze the complexity of within-group differences (i.e., not all people within a certain class or SES are assumed to share the same characteristics). This model specifically addresses the subjective experience of SES most often known as social class. This has important implications for counseling, as clients' and counselors' perceptions of both their own and the others' SES impact the counseling relationship and process.

Liu chose a worldview model because the underlying construct he is describing reflects people's subjective experience of belonging to a specific group. The subjective context of the SCWM is one's perceived class and status position. This influences saliency, consciousness, and attitudes toward social class issues, which interact with referent groups, material objects, lifestyle, and behaviors. Though all aspects of the SCWM influence one another, saliency, consciousness, and attitudes are placed at the center of the model. *Perceived class and status position* is a person's answer to the question, "What is your social class background?" *Saliency* indicates a level of awareness of an SES system in which there are differential opportunities for people in different classes. *Consciousness* refers to the level of awareness an individual has about belonging to, and being influenced by, a social class system. *Attitudes* refer to feelings, beliefs, attributions, and values about social class. Social class attitudes are shaped by one's early socialization experiences.

*Referent groups* are groups that inform one's socialization experiences. They influence the development of the SCWM and one's behaviors. The three referent groups that Liu names are the *group of origination* (e.g., caretakers, relatives, early peers), *cohort group* (those with whom one spends the most time and are most similar to him or her in their own worldview and behavior), and *group of aspiration* (the group that one would like to belong to). *Material objects*,

*lifestyle*, and *behavior* can be considered “performance” variables, as they are the visible indicators of class and status. Liu discussed the objective SES measures of income, occupation, and education as limits on one’s SCWM. One’s class aspirations may not match one’s resources.

Because of the paucity of research on the subjective experience of social class, this is a preliminary model that has not been validated. The SCWM places a person’s subjective interpretations of social class in ecological context by considering cultural values, social comparison groups, and other important systemic variables. It is a promising paradigm for understanding how people make sense of social class.

Lott, Smith, and Liu each have made significant contributions to the understanding of the relevance of SES to counseling. In U.S. society, the ideology of the “American dream” reinforces a cultural myth that there is no class stratification and that anyone can climb the social class ladder with effort. An understanding of class-based oppression is crucial for counselors who may be working with individuals from different SES groups. More often than not, counselors hold a relatively high SES in U.S. society because of their education and occupational prestige. It is crucial for counselors to examine their SES and social class biases, in addition to examining biases based on race, gender, and other social identities. Liu’s model offers a helpful framework for counselors to ask themselves questions about their SES-related beliefs, attitudes, and behaviors. It also provides a model for understanding how social class may be related to clients’ presenting concerns. Because social class and SES are complex and often misunderstood constructs, models such as the SCWM can provide structure to the examination of these issues.

### Future Directions

SES and social class are inadequately defined in social science research, including counseling research. Socioeconomic indicators such as income, wealth, occupation and occupational prestige, and education have clear implications for health and mental health and will benefit from further research. In addition, counseling psychologists have begun to address the subjective meaning of social class and how it plays out in their lives, including in counseling relationships. An important aspect of this research will focus on understanding discrimination and oppression

based on SES and how it affects the work of counselors and psychologists.

## SOJOURNER

---

A sojourner is a person who resides in a country other than his or her country of origin for an extended time. Sojourners leave their home country for a specific purpose (e.g., teaching, studying, working, military service, humanitarian aide) but have no intentions of applying for citizenship or moving permanently to the host country. International students, peace corps volunteers, military personnel, missionaries, and people who temporarily work overseas are all examples of sojourners. Usually this temporary move is purely by choice; however, in certain cases, like that of military personnel, their service may be voluntary but their requirement to move may be a demand of their service and thereby not totally of their own accord. Sojourning has become increasingly popular as technology and communication have advanced to create a global economy.

Sojourning can be considered a major life stressor and individuals may see a counselor for assistance in adjusting to their relocation. Cognitive, behavioral, and emotional adjustment will be necessary. Upon arrival in their host country, many sojourners describe a variety of symptoms such as fatigue, isolation, numbness, irritability, confusion, a sense of loss and/or violation, frustration, anger, exhaustion, depression, and reduced confidence. These tend to be most prevalent upon their arrival in the host country and dissipate over time. A failure to recover from the transition into another culture may result in an early

return to their native country, difficulties performing their duties in the host country, and prolonged distress. This failure to adjust may have long-term effects on their career path and interpersonal relationships. Counselors can assist their clients by helping them adjust to their new environment and normalizing their feelings. Counselors must be respectful of their unique worldview and not suggest they change to fit in with the culture of the new country. It is important to understand what the sojourner's expectation is for counseling and how counseling is viewed in his or her country of origin. This will be critical in determining the client's expectations of the counselor. Sojourners may present many challenges to the counselor, such as less fluency in the host culture language, different nonverbal behaviors, and different customs. It is necessary for counselors to familiarize themselves with the customs of their culture of origin to facilitate a multiculturally sensitive approach to treatment.

If sojourners are able to negotiate the adjustment into their host culture, they may return to their native country having gained a new understanding of international relations and an increased appreciation for both their native country and their host country.

## SPIRITUALITY

---

Spirituality, from the Latin *spiritus*, refers to a sense of, or belief in, something bigger than, beyond, or outside oneself. Individual spirituality is often seen as a

connection among oneself, others, and that which is beyond oneself and others. In addition, some scholars have referred to spirituality as a holistic connection with the divine or the breath that animates life. Some see spirituality in terms of people's attempts to understand the ultimate nature of things in the universe; in this way, spirituality shares commonalities with some philosophies. Finally, others relate spirituality to psychological health; that is, the person on a spiritual path is also seeking psychological balance and well-being.

Spirituality is often combined and/or confused with religion. There is a lack of consensus among professionals regarding the similarities and differences where spirituality and religion are concerned, which has resulted in a frequent merging of the two constructs. There are, however, some agreed-upon ways to articulate the differences between spirituality and religion. For example, spirituality has been seen as encompassing religion; that is, religion is a form of spirituality. In addition, spirituality is typically seen as a construct that resides within an individual and connotes a personal relationship with a higher power. In contrast, religion is a social institution, with rules and hierarchies for salvation. As a result of this difference, religions tend to proscribe a path to enlightenment or nirvana, while the spiritual person would suggest that there are many ways to achieve the desired goals regarding psychological and spiritual well-being.

### **Manifestations of Personal Spirituality**

There is no one "right" way to be spiritual. To that end, spirituality can be demonstrated in a variety of ways. Some examples of personal manifestations of spirituality include prayer, meditation, yoga, physical exercise, laughter, breathing exercises, worship, rituals, fasting, imagery creation, Bible/Qur'an/Talmud study, pastoral counseling, and quoting sacred texts. It is important to note that this list is not meant to be exhaustive.

### **Spirituality in the Counseling Process**

Like many things in a counseling relationship, the spirituality of the counselor and client can significantly impact the therapeutic process. The spiritual beliefs of both the therapist and the client should be viewed as important characteristics that may affect counseling.

For clients, their spirituality should be considered as important to the therapeutic process as any other salient variable, especially clients for whom spirituality is

central to their identity or cultural self-description. For some clients, spirituality provides a lens or worldview with which they see and interact with others in their environment. For highly spiritual clients, then, counselors should be sure to attend to the client's spiritual orientation, as it is likely to facilitate the client's exploration of the problem(s) that brought him or her to counseling. In addition, counseling professionals will obtain a more complete understanding of their clients by attending to the client's spirituality. Of course, some clients might not feel comfortable talking about spirituality with their counselor because they might assume that spirituality is a taboo topic in counseling.

For counselors, there are two conditions in which spirituality affects the counseling process. First, the counselor can facilitate the client's disclosure by welcoming, and perhaps even inquiring about, the client's spirituality in session. In this way, the counselor must provide a safe environment for the client to discuss his or her personal spirituality. Honoring the client's spirituality can be as effective as being empathic and sensitive to the client's other aspects of identity, such as race, ethnicity, gender, sexuality, religion, and socioeconomic status.

Second, the personal spirituality of the counselor can also assist in the development and strengthening of the counseling relationship. For example, many counselors endorse having spiritual beliefs that serve as guiding principles for their lives. This view of self and others can be facilitative with regard to the counselor's understanding and conceptualization of the client's behavior, history, and worldview. The counselor who understands the role of spirituality in his or her own life, even if that means no spirituality, will be better prepared to attend to the client's personal spirituality as it might emerge in the counseling process.

Effectively discussing spirituality between the counselor and client has the potential to establish a sound working alliance, especially where there is some shared perceptions regarding spirituality. Through the counselor's welcoming of spirituality into the treatment room, the client may feel more comfortable in disclosing those aspects of him- or herself, especially as they relate to the presenting problem(s). At the minimum, counselors should attend to the client's spirituality if and when the client raises that issue as part of the counseling process. To ignore a client's sense of spirituality is to deny what could be a vital, if not central, aspect of the client's identity. In sum, clients will be better served by counseling professionals who attend to spirituality in their clients

and who have sought to understand what role, if any, spirituality plays in their own lives.

### Spirituality in the Lives of People of Color

It is important to attend to spiritual concerns in all clients; however, with clients of color it may be even more critical to understand the role that spirituality plays in their lives. Continuous experiences with social intolerance (i.e., prejudice, racism, discrimination, and oppression) have been primary forces causing a deepened level of spirituality for many people of color. These forces, both powerful and harmful, often have negative psychological impacts; some examples include heightened levels of anxiety, frustration, depression, and identity confusion. As a result, people of color seek refuge from this intolerance through spirituality; this is done to comfortably connect their internal selves with the surrounding world and a self-defined higher power or higher being. Through personal spirituality, people of color find ways of transcending difficult social situations and recognizing the positive aspects of unfortunate circumstances. Hence, spirituality plays an integral part in the lives of people of color by empowering them with renewed hope and strength to endure despite daily personal and social struggles.

### Spirituality as a Coping Mechanism

Spiritual practices and beliefs are relevant across all racial and cultural groups, providing coping mechanisms for a variety of stressors. The use of spiritual techniques may help people view difficult or challenging situations in a more positive light by identifying personal meaning in the face of adversity. This could, in turn, lead to acceptance and possibly appreciation of negative experiences. Belief in a higher power may also serve as a powerful resource for clients in terms of feeling supported in the face of struggles. In sum, embracing spirituality can be a powerful tool for building personal strength and enhancing resiliency for the challenges of daily living.

## STEREOTYPE

Stereotype is generally defined as a consciously or unconsciously held rigid belief or expectation about a group that does not easily permit exceptions. Stereotyped beliefs are held by a group (commonly called the ingroup) and involve an agenda that benefits the ingroup at the expense of the stereotyped group (commonly called the outgroup or target group). Stereotypes help the ingroup members feel good about their group and themselves relative to the target group. A stereotype often concerns a trait that is important to the ingroup's identity and emphasizes the distinctness and inferiority of the outgroup. Relatedly, stereotypes maintain sociopolitical hierarchies in society. They can serve as a justification for believing that certain groups are superior to others and as a rationale for oppressing target groups.

While the phenomenon of stereotyping has been defined and explored primarily in social and cognitive psychology, it has many implications for counseling and has been taken up and discussed by many scholars in counseling psychology. These discussions often focus on the sociopolitical aspects of stereotypes,

including the relevance of stereotypes to prejudice and to counseling training, competence, and process.

### History of the Term

The term *stereotype* comes from two Greek words meaning “solid” and “a model.” In English, it first meant a metal printing plate. The term evolved to become associated with the act of stamping out the same image or text over and over; by the beginning of the 20th century, it connoted rigid, repetitive behavior. Soon thereafter it was applied to cognitive processes of categorization that were consistent and predictable. Early discussions of categorizing objects asserted that stereotypes were useful but also resulted in a certain number of errors. When applied to the social domain in the 1930s, *stereotype* came to denote the misattributions commonly applied to ethnic groups (e.g., Germans are scientific minded; Turks are cruel). Thus, stereotypes became linked to prejudice and discrimination and were often considered negative. At this time stereotypes ceased to involve exclusively errors in cognition and became a social phenomenon resulting more from cultural influences than from individual experience.

In the latter 1970s and the 1980s scholars began exploring the cognitive processes of stereotyping, relating stereotypes to cognitive schemata or theories. Using general principles of cognitive processing to illuminate how stereotyping occurs, the discussion at times ignored the sociopolitical context of the phenomenon. In contrast, when the field of counseling took up the term in examining the impact of prejudice and ethnocentrism on counseling process and training, scholars consistently focused on the sociopolitical underpinnings of stereotyping.

### Perspectives on Stereotyping

In discussing stereotyping, counseling scholars often draw heavily on conceptualizations generated by other fields. A discussion of these perspectives can flesh out the phenomenon’s meaning for counseling.

#### ***Stereotyping as a Social-Cognitive Phenomenon***

Stereotypes have been explored a great deal in terms of the cognitive processes of attending to, organizing, and interpreting social information or stimuli encountered in everyday life. Social psychologists have done the majority of this work, applying principles

of cognitive psychology to social stereotyping. The premise is that people do not have the capacity or resources to consider and analyze every new stimulus as if it were the first piece of information ever received. To process all incoming stimuli efficiently and effectively, people create sorting mechanisms, expectations, and assumptions, often called *cognitive schemata*. Schemata are systems that help people make sense of the complex sets of stimuli that constantly confront them. Schemata are organizing principles that prioritize what to focus on and that categorize and organize the information for interpretation. For example, we have a schema that helps us efficiently differentiate a table from a chair based on multiple expectations about the attributes of each of these objects. From a social-cognitive perspective, stereotypes are a type of schema—rules and expectations we have about people from different groups.

Schemata often become automatic and unconscious. Thus, stereotype holders are not often aware of the expectations and assumptions that influence their thinking, emotions, and behavior. When asked explicitly, they deny holding these stereotypes, but the stereotypes manifest their influence in implicit ways.

Often, the experiences that give rise to stereotyped beliefs are also implicit and embedded in a society’s culture. Implicit messages that give rise to stereotypes are broadcast by societal institutions. For example, the media do not explicitly state that Whites or men are superior to people of color or women, but they present a preponderance of heroic characters that are White men, while presenting people of color and women in secondary and supporting roles. This imbalance in portrayals communicates stereotypes about racial and gender hierarchy, including that White men have greater abilities and are more important than people of color and women. As a result, many members of the society unconsciously hold such stereotypes.

To understand stereotypes, social-cognitive scholars have drawn on rules for how unconscious cognitive sorting and organizing processes function. For instance, based on rules of human cognition, groups that stand out (e.g., groups who are in the minority and are judged to be different from the majority) and traits that stand out (e.g., traits that are not often seen in mainstream experience) are often paired to form stereotypes. In the example, Blacks stand out as a minority group visibly distinguishable from Whites, and criminality stands out as an infrequent, deviant trait, so the two can be connected easily in the White person’s mind. Even though the connection does not

exist in reality, the distinctiveness of both the group and the trait creates fertile ground for them to be paired in a stereotype.

Of course, stereotyping is a social as well as a cognitive process. The culture, characteristics, and views of the ingroup are important in the development of stereotypes. Fertile ground for a stereotype is increased if the target group is viewed as deviating from the ingroup on the trait in question. It is also increased when the trait is one that the ingroup deems important to its identity. To most Whites, not being a criminal means that one has the favor and help of society's institutions (e.g., the police), and thus one has more value and power in society. Thus, the stereotype that Black and Latino males are criminals can serve to make Whites feel more valuable and powerful by creating a false contrast on an attribute or status that is important in White culture.

Stereotypes also have an emotional component. If an ingroup has strong negative feelings about a trait they perceive in a target group, a stereotype is likely to develop. The in-group's emotions about the target group also come into play: Greater negative feelings toward the group can result in more negative stereotypes about the group. In fact, simply putting people in a bad mood has been shown to elicit more stereotyped judgments of others.

This emotional component of stereotyping contributes to a vicious cycle. When ingroup members experience what they perceive as a negative encounter with target group members, they develop negative feelings about the target group and what they perceive as its undesirable traits. This gives rise to increased negative feelings and expectations (stereotypes), which influence their interpretation of and reaction to future encounters, resulting in further affirmation of the stereotype.

The social-cognitive approach also helps explain why stereotypes are rigid and hard to change. People are more likely to process accurately and remember information that is consistent with stereotypes they hold. Many studies have shown that stereotype-consistent information is easily remembered and readily accepted without question. People also tend to remember (but with a different purpose) information that is contrary to the stereotypes they hold. They pay very close attention primarily to figure out how to explain or interpret the information so that their stereotype remains unchallenged. The new information may be distorted or misperceived to fit the stereotype.

Of course, new information can cause a person to modify or even abandon a stereotype, but this happens

only rarely. From a cognitive perspective, people tend to see what fits with what they expect, and they often misperceive what is there, to fit their expectations. This happens in categorizing or characterizing objects as well as people. When this cognitive tendency is added to the emotional component of stereotypes and to the individual and group dividends gained by maintaining a stereotype, it is clear why contrary information often does not produce a change in a stereotype.

One way in which evidence contrary to a stereotype is absorbed without threatening the hold of the belief involves the process of subtyping. People create a slightly different subcategory of the larger target group to hold an individual member of the group who presents with traits that are inconsistent with the stereotype. For example, to absorb the fact that many Blacks are successful and law-abiding, Whites create subtypes (Black businessperson, educated Black), while maintaining the general negative stereotype that Blacks are criminals.

Contrary information may also be processed as extreme: The perceiver may tend to exaggerate the level of the unexpected trait or behavior. Thus, a woman who is competitive or ambitious is seen as extremely (and negatively) so, whereas a man with the same level of these traits is seen as normal. Similarly, stereotypes may create what is called a *shifting standard* for judging the behavior of individuals from different groups. For example, if a teacher who holds the stereotyped expectation that Blacks are less intelligent than Whites sees the same test score from a Black and a White student, the Black student may be perceived as highly intelligent and the White student as of average intelligence. Due to the stereotype, the teacher maintains a lower standard for considering a Black student intelligent than for considering a White student intelligent. The Black student will be perceived as very smart *for a Black person*.

The social-cognitive perspective helps counselors understand the functioning and even some of the motivation behind stereotypes, but it is also limited because it more or less views stereotyping in a political vacuum, as if no power hierarchy of social groups existed. Stereotypes play a role in rationalizing and maintaining this hierarchy, and the hierarchy influences the nature of stereotypes.

### ***Stereotyping as a Sociopolitical Phenomenon***

Counselors draw upon the social-cognitive approach to stereotypes but often integrate it into a

larger context. Sociopolitical factors and cognitive factors interact in both developing and maintaining stereotypes. Stereotypes emerge from the sociocultural context and are driven by power differentials between groups. As noted earlier, the distinctions between groups that are inherent in stereotyping can make the ingroup feel better about itself. To push further on this point, counseling has tended to look at the role of stereotypes in reinforcing power hierarchies between reference groups.

From the sociopolitical perspective, stereotypes grow out of a need to rationalize oppression and subjugation rather than simply out of cognitive processes and errors. For example, in the service of enslavement and genocide, stereotypes emerged that Blacks were childlike and Native Americans savage. Thus, sociopolitical expediencies influence the traits misattributed to a group.

Sociopolitical influence is illustrated by the change in stereotypes held about Blacks before and after slavery was abolished. Before abolition, Blacks were stereotyped as docile, dependent, and incapable of independent thought or action, that is, a group seen as benefiting from enslavement. After slavery was abolished, however, the Whites' stereotype of Blacks tended toward aggressive, dangerous, wild, and uncontrollable. The belief in these traits played a role in justifying brutal treatment of Blacks by Whites both by law (e.g., Jim Crow statutes) and outside the law (e.g., lynching). Thus, the existence and nature of stereotypes can change based on the ingroup's requisites for protecting its privilege and access to power and resources.

Such change suggests that stereotypes may not originate in experience. An initial negative encounter with a target group may not be necessary for a stereotype to develop. Some argue that sociopolitical forces give rise to stereotypes first, and then social-cognitive processes come into play, contributing to their maintenance and rigidity. Power differentials between groups, and the need to rationalize them, may be the starting point for the vicious cycle discussed earlier.

## Implications for Counseling

### ***Impact of Stereotypes on the Counseling Process***

Among other things, counseling involves evaluating clients and their experiences, to gain an empathic understanding and choose appropriate interventions. Stereotypes have a deleterious effect on this process in several ways. First, they set expectations that limit the

counselor's openness to who clients are and what they are experiencing. If a counselor expects a female client to be weak and submissive, the counselor is more likely to ignore or misinterpret information suggesting the opposite. The counselor will misunderstand the client and impose this expectation on her. Such a response can invalidate the client's experience and even negatively influence her sense of who she is. If, due to a counselor's stereotype, a certain trait or experience of a client is always ignored, while evidence of another trait is always emphasized and focused on, the client may start to believe and behave as if the stereotype were true. Counseling scholars have noted that this is a form of oppression and must be avoided in counseling practice.

Even when counselors recognize information contrary to a stereotype, they may distort the information and the relationship. A counselor who holds stereotypes about female gender roles (that women are "feminine" by nature) and encounters "masculine" traits in a female client may perceive those traits as exaggerated, resulting in a distorted view of the client. Or a counselor may not take seriously a successful Black client's vocational concerns if the counselor perceives that the client has achieved great success *for a Black person*. Holding this lower standard for certain groups has broad implications in areas within the counseling realm. At the individual level a school counselor may not encourage a Black student to pursue college, and at the institutional level, the allocation of resources to these groups will match the low standard of performance expected from them.

Stereotyping can lead to nongenuine and condescending relations between counselor and client. Because it is socially unacceptable to stereotype openly, White guidance counselors may evaluate the performance of Black students less critically in an attempt to avoid being perceived as stereotyping. Although this behavior may even come out of a desire to counteract racism (though it may also arise out of a motivation not to *appear* prejudiced), in essence it perpetuates prejudice and the stereotype by implying that the target group should be held to a lower standard.

Most people are not aware of the stereotypes they hold. Because stereotypes are unconscious, a counselor will perceive the aforementioned evaluations of clients as objective and perhaps not even linked to group membership. Thus, communication of the stereotype from counselor to client may be implicit and highly subtle, making it hard for either party to identify and counter. In fact, stereotypes often set off

subtle, unconscious interactive patterns between the stereotype holder (counselor) and the target (client). The counselor's expectations create both a cognitive and an emotional disposition toward the client that may be subtly communicated to the client through nonverbal and other behavior. The client may well respond to these cues in ways that the counselor interprets negatively according to the stereotype. The counselor, unaware of the impact the stereotype has already had on the client's behavior, concludes that the client's behavior represents clear evidence for the truth of the stereotype. Again, the vicious cycle ensues.

### ***Stereotypes and Multicultural Counseling Competence***

The multicultural counseling competencies specifically mandate that counselors be aware of the stereotypes that they hold and the impact these beliefs have on their work with clients. This implies that most, if not all, counselors hold stereotypes and must become aware of them and avoid their negative effects.

Some counseling scholars note that counselors must eliminate the negative effects of stereotypes to become culturally sensitive, an attribute mandated by the American Counseling Association's code of ethics. The inverse relationship between cultural sensitivity and stereotyping can be seen when one considers stereotypes as a type of cognitive schema.

Schemata can be seen in two ways. On the one hand, they are flexible hypotheses that can be influenced by information coming in. For instance, when a piece of information is not accounted for by an existing schema, the schema may change and adapt to incorporate the new information. If a schema for chair is flexible, a newly encountered bean bag may be considered a chair. Scholars assert that flexible schemata about social groups characterize cultural sensitivity.

On the other hand, schemata can be rigid expectations that influence what is perceived and how it is interpreted. They can impose a selective focus on incoming stimuli and prioritize information that poses no threat to the schema. Such schemata also affect how stimuli are interpreted, so even contradictory information may be interpreted in a way that supports the schemata, and the meaning of the information is distorted. Counseling scholars note that such rigid information processing is the basis of stereotyping.

Some counseling scholars state that, if counselors apply any stereotype of a particular group to all its individuals, the counselors are likely to misperceive

and misunderstand the clients and fail to be culturally sensitive. Stereotypes block interpersonal communication and rapport; they can lead clients to early termination, alienation from the counseling process, and cultural oppression. To avoid these errors and outcomes, scholars suggest that counselors work to become more conscious of their information processing in client encounters and treat expectations as hypotheses whose fit with the particular client must always be evaluated. Such caution should be exercised even when counselor and client are members of the same group, as within-group variance may make automatic expectations erroneous.

In overcoming the negative impact of stereotypes on the counseling process, and promoting culturally sensitive counseling, counselors critically need self-awareness of their own cultural and group memberships and their influences on their expectations. Self-analysis should include exploring the origins of, and possible motivations behind, each expectation, bringing these to consciousness. Only then can they be held as hypotheses to understand others' experiences and behaviors rather than rigid stereotypes kept in place by unknown agendas.

A self-aware counselor can be purposive and active in applying schemata to work with clients. An unexamined, passive, automatic application of schemata is likely to result in stereotyping the client. Counselors must actively explore and intentionally direct what stimuli they attend to, how they interpret the information, and what they do based on the information. Because many counselors have been socialized not to attend to group membership issues, inattention is the default. Inattention allows unexamined stereotypes to hold sway over what is acknowledged and how it is responded to.

Some counseling scholars, noting that stereotyping provides the ingroup with a self-definition distinct from and superior to that of the target group, assert that asking counselors to stop their stereotyping behavior is akin to asking them to give up a source of positive self-regard. They suggest that such work must be done in a safe environment and must include help in breaking down the connection between anti-target group sentiment and beliefs and positive self-construal.

### ***Impact of Stereotypes on the Target Group: Stereotype Threat***

Another effect of stereotyping on the counseling process is the impact on targets. Counselors must be

aware of how stereotyping affects the ways both counselors and their clients present. Such understanding can help counselors develop interventions, especially at the programmatic level, that can mitigate the negative impact of stereotypes.

One impact that has been extensively explored is the phenomenon of stereotype threat. Stereotype threat is a situationally triggered phenomenon in which a target group member's efforts to avoid confirming a stereotype lead to performance deficits. Stereotype threat can arise when a target group member approaches a task for which a stereotype expects poor performance by the target group. The individual tends to experience pressure to disconfirm the stereotype. Cognitive resources are marshaled to deal with this pressure, so they are not available for completing the task, and this negatively impacts performance. For example, when a female science student takes a biology exam she may be hampered by pressure to disconfirm the stereotype that women are not good in science.

The negative effect of the stereotype goes beyond the poor performance. It can cause target individuals to avoid domains in which a stereotype exists and their behavior may be evaluated. This can cause targets to avoid certain majors or fields, or even avoid speaking in class.

Thus, simply by their existence, stereotypes can produce the behaviors that they predict in target group members. An ingroup member need not react to a target based on a stereotype for the target to experience a negative effect. To mitigate these negative effects, counselors must do more than simply be aware of the stereotypes they hold and limit the negative effects of those on counseling. Scholars suggest that programs and interventions must reduce the stereotype threat experienced by targets. First, counselors must avoid ascribing clients' difficulties exclusively to internal processes such as the internalization of stereotypes by targets. Modification of contextual and situational factors must also be considered important avenues for intervention. Second, programs and interventions must avoid being a source of stereotype threat themselves. Threat can occur when a program or intervention is presented as remedial, suggesting that those who need this intervention are inferior. Targets may often be identified as having a problem and be referred to programs created to help them. Participation in the program can then be seen as a confirmation of a stereotype. One suggestion is that programs and interventions be modified to challenge participants sensitively, rather than

lowering the expected standard. Participation, too, must be reframed as an earned privilege, showing that the client is up for the challenge, rather than a punishment for poor performance. Such programs and interventions actively counter the stereotypes in the air and create an environment where participants can feel proud of both their group membership and their efforts in the domain of their choice. Pride can create a positive linking of these two in the perception of all, countering stereotypes as well as their negative impact.

---

## STEREOTYPE THREAT

---

In 1995, Claude M. Steele and Joshua Aronson coined the term *stereotype threat*. The cornerstone of the phenomenon of stereotype threat is the pressure to not conform to a given expectation of poor performance. This results in an activation of negative and internalized stereotypes. In other words, the pressure to not conform to a known negative stereotype about the group with which one identifies can result in compromised performance on a said task.

Steele and Aronson first examined stereotype threat among African Americans. One negative stereotype toward African Americans is low intelligence; when intelligence is defined as fixed, it creates a belief that innate or biological limitations may be to blame for poor performance. Unfortunately, these stereotypes have been applied wrongly to explain the achievement gap between African Americans and Caucasians on standardized test scores. Steele and Aronson's 1995 study created a scenario characterized by stereotype threat, where this stereotype was made salient by telling the treatment group that the test they were taking measured intelligence. The control group was told that the test was a measure to study problem solving. When stereotype threat was absent, the scores of the African American students only differed to the degree that would be expected on the basis of their prior Scholastic Aptitude Test (SAT) scores. When stereotype threat was present, the African American students performed worse than the Caucasian students. The difference was beyond what prior SAT scores would predict for individual differences in skill level. Stereotype threat was shown to be a condition where negative stereotypes about a group identity are evoked and individuals are in a situation where they could conform to that stereotype. In the previous

example, the suggestion that the test was a measure of intelligence invoked the stereotype that African Americans have lower intelligence for the African American students and under the pressure of the possibility of confirming this stereotype, they actually performed worse than would have been expected. The stereotyped group does not have to believe the stereotype for this effect to materialize.

## Generality

Stereotype threat can be generalized to populations where stereotypes are present. Numerous studies have confirmed the presence of stereotype threat among diverse racial groups, ethnicities, genders, socioeconomic statuses, and age groups. In an article published in 1999, Aronson, Michael Lustina, Catherine Good, and Kelli Keough demonstrated that stereotype threat can be present in groups that do not have a history of stigmatization or internalized feelings of inferiority. Their study found that White males performed worse on a math test than their control group counterparts when it was suggested that Asians are better at math. It seems reasonable that all groups have a negative stereotype that can be made salient in circumstances where there is pressure to perform.

Much of the research focuses on test performance; however, there have been studies confirming that stereotype threat could be induced in other domains as well. For example, a 2005 study done by Paul Davies, Steven Spencer, and Steele confirmed that exposure to gender stereotypes about leadership affected female participants' interest in taking on a leadership role. Women who had been exposed to the negative stereotypes about women's abilities in leadership were less interested in assuming a position of leadership on the task.

## Consequences

Consequences of stereotype threat are numerous. It can create a setting where a socially constructed concept can interfere with the measurement of constructs such as intelligence. Currently, high-stakes testing is used as a gatekeeper to many educational opportunities. Stereotype threat may have a role in lower test scores, which in turn may function to keep people from gaining access to opportunities. Although the concept of stereotype threat has been studied most in the area of academic achievement and the achievement gap, stereotype threat may evidence in other

contexts such as work performance. Second, this concept demonstrates how powerful stereotypes are and what the impact of internalized negative stereotypes is. Stereotype threat may create a scenario where there is now a vicious cycle. For example, a person knows of a stereotype for his or her group and, feeling pressured to not conform to a negative expectation for this reference group, the person's performance on a given task suffers: The person may be denied entrance to the school of his or her choice, or the person may miss other opportunities like jobs or community leadership roles. This denied opportunity can contribute to social inequities, including the achievement and wage gaps. In essence, this concept is critical to understanding the complex effects of stereotyping on performance. There are also effects on self-esteem and confidence for those who perform under their expectations. Many people may not be aware of stereotype threat and may begin to believe that their lower performance was a result of personal characteristics.

### Mediators

Aronson and Steele published a chapter in 2005 that explored potential mediators of stereotype threat on test performance. Anxiety has been found to be a mediator as negative stereotypes are posited to create more anxiety. The knowledge of a negative stereotype can produce anxiety, which can hinder performance. Stereotype threat can be enacted most powerfully by individuals who care strongly about doing well in a particular domain. Stereotype threat poses a particular jeopardy because it seems to be present even in situations where the student is actually motivated and interested. For example, a female student who wants to attend the best university to study math can do poorly on the math section of an entrance exam because of stereotype threat (i.e., the negative expectation that is operative is that women are not adept at math).

Individuals who have a strong identification with their group are more likely to be aware of the stereotypes about their group. Thus, research has found that people who are the most identified with their group are more affected by stereotype threat. For example, a Latino/a who is highly identified with his or her ethnic group is affected more by stereotype threat than a Latino/a student who does not identify highly with the group. However, that same student may identify highly with being lesbian or female, and therefore

stereotype threat may be more salient for the stereotypes about lesbians or females.

In the context of competition among reference groups, stereotype threat can be induced in individuals who believe they are good at the particular exercise. For example, Steele and Aronson showed that stereotype threat can be evoked for White males if they are being compared to a group, such as Asian Americans, who are stereotyped to excel at math. See Aronson and Steele (2005) for a comprehensive review of some of the research results that led to these conclusions.

### Relevance to Cross-Cultural Counseling

The phenomenon of stereotype threat is relevant to cross-cultural and multicultural counseling in several ways. First counselors need to be aware of the stereotype threat and how it works, as they may evoke stereotype threat through subtle words and/or behaviors when administering tests or during the actual process of counseling. Also, counselors may be in a position to educate those that they come in contact with about the phenomenon so that steps can be taken to reduce the likelihood of stereotype threat occurring.

---

## SUE, DERALD WING (1942– ): CONTRIBUTIONS TO MULTICULTURAL PSYCHOLOGY AND COUNSELING

---

Derald Wing Sue is a pioneer and leader of multicultural psychology, counseling, and therapy. He is professor of psychology and education at Teachers College, Columbia University, and contributes extensively to the field through his teaching, publications, research, consultation, and organizational work.

Sue graduated with a Bachelor of Science degree in psychology from Oregon State University in 1965 and received his Ph.D. in counseling psychology from the University of Oregon in 1969. He was formerly professor at California State University East Bay (then California State University Hayward) and at Alliant International University (then California School for Professional Psychology).

Sue's extensive body of work has been pivotal in transforming psychology to be inclusive of cultural considerations in multiple domains, including theory, research, education, training, and practice. Sue has been honored numerous times for his contributions and work on multiculturalism and cultural diversity, and he has received awards from many organizations, including the American Psychological Association, the Association for Multicultural Counseling and Development, the Asian American Psychological Association, the Society for the Psychological Study of Ethnic Minority Issues, the American Counseling Association, and the American Academy of Counseling Psychology. In addition, Sue is a Fellow of the American Psychological Society, the American

Association of Applied and Preventive Psychology, and the American Psychological Association (Divisions 1, 17, and 45), as well as a member of the American Counseling Association.

### Research and Teaching

Sue's research and writings on multicultural issues in psychology have led and challenged the field of psychology to examine and critique the Eurocentric basis and assumptions of its fundamental theories, concepts, frameworks, and practices. Before the early 1970s, cultural variables were generally ignored in the field of psychology, and there was scarce research on Asian American psychology. During this time, Sue was a pioneer in the study of Asian American mental health when he collaborated with other researchers to study different aspects of Asian American psychology.

Sue's research efforts span his earliest work in Asian American psychology, to his contributions to multicultural competencies and multicultural theory, and, most recently, his research on racial microaggressions (i.e., the brief and everyday exchanges that send denigrating messages to people of color because of their racial minority status). Sue argues that racial microaggressions sap the spiritual and psychological energies of people of color and create disparities in education, health care, and employment.

Sue also has been a trailblazer in the arena of multicultural counseling teaching and training. As a young professor in the early 1970s, he developed multicultural counseling courses and infused multicultural content into other counseling courses. These courses were initially met with heavy opposition at multiple levels but have now become standard requirements in graduate clinical and counseling psychology training programs.

Sue's teaching contributions are not limited to academia, as he has provided cultural diversity training and consulted for many organizations, from Fortune 500 companies to nonprofit mental health agencies all over the world. Most notably, Sue served as a consultant and invited panelist on President Clinton's Race Advisory Board on the National Dialogue on Race in 1997, in which he called for individual, institutional, and societal efforts to confront and address racism, injustice, and discrimination. Sue also participated in a congressional briefing on the psychology of racism in 1995.

## Writing and Publications

In 1981, Sue wrote and published the seminal textbook, *Counseling the Culturally Diverse*; his brother David Sue joined him as coauthor of subsequent editions. Initially criticized for its sociopolitical content, the book has become a classic in the field and is the textbook of choice for almost 50% of graduate counseling psychology programs. Now in its fifth edition, the book also has the distinction of being one of the most frequently cited references in multicultural counseling and therapy. Sue also has authored and coauthored many articles and books that have been the impetus for the field of psychology to adopt the multicultural competencies as guidelines. These books include *A Theory of Multicultural Counseling and Therapy* (cowritten with Allen Ivey and Paul Pedersen in 1996) and *Multicultural Counseling Competencies: Individual, Professional and Organizational Development* (coauthored with members of the Division 17 and Division 45 multicultural committees in 1998). Sue's 2003 book *Overcoming Our Racism: The Journey to Liberation*—a trenchant and hard-hitting call to Whites to acknowledge and take responsibility for their racism—was the direct result of his testimony before President Clinton's Race Advisory Board.

Sue also has written 13 textbooks on personality theory, introductory psychology, racism, and abnormal behavior. These textbooks are distinctive in presenting the subject of psychology through a multicultural framework. Most notably, Sue has challenged prevailing notions of universals of mental health, instead advocating for an understanding of cultural variables in the conceptualization, assessment, and treatment of mental illness. His work also has been featured in other media formats; for example, he has produced several videotapes on racism and psychology, including *The Psychology of Racism: Where Have We Gone Wrong?*; *What Does It Mean to Be White?*; *The Invisible Whiteness of Being*; and *Overcoming Our Racism: What Can I Do?*

## Contributions to Professional Organizations

Sue has played an active role in the leadership of many professional organizations, including serving as president for the Society for the Psychological Study of Ethnic Minority Issues (Division 45) from 1998 to 1999 and the Society of Counseling Psychology (Division 17) of the American Psychological

Association) from 2003 to 2004. With his brother Stanley Sue, Sue cofounded and became the first president of the Asian American Psychological Association (AAPA) in 1972. AAPA's mission was to promote the study of Asian American mental health and culturally appropriate interventions and to support the training and education of Asian American mental health professionals. Since its inception in 1972, AAPA has grown into a sizeable organization with more than 400 members.

In the 1980s and 1990s, Sue chaired two committees working to develop multicultural competencies for the counseling field. The work of these two committees was published in 1982 and 1998, and the competencies generated by these committees formed the foundation for the adoption of multicultural guidelines by the American Psychological Association in 2002. The concept of multicultural counseling competencies has been profoundly influential in shaping the training, education, and accreditation of counselors, therapists, and psychologists. As a result of these competencies, graduate psychology training programs have been revamped to include multicultural counseling courses in their curricula and to infuse cultural considerations into existing coursework.

In addition to his leadership contributions to various professional organizations, Sue also has held numerous editorial posts, including serving as the first Asian and non-White editor of the *Personnel and Guidance Journal* (now the *Journal of Counseling & Development*). As the editor for the *Personnel and Guidance Journal*, he was innovative in his efforts to include articles that were culturally inclusive, systemically oriented, and prevention focused. These unprecedented efforts were met with tremendous support from some groups and deep resistance from others.

Sue also played a key role in the collaborative effort to organize the National Multicultural Summit in 1999, a conference focused on issues of multiculturalism and diversity. The creation of the summit was one of Sue's presidential initiatives when he was elected president of the Society for the Psychological Study of Ethnic Minority Issues (i.e., Division 45 of the American Psychological Association) in 1998. This was a historic moment in the history of psychology because Sue was one of four people of color that year elected to leadership positions within the American Psychological Association. (Sue was elected as president of Division 45, Rosie P. Bingham was elected president of Division 17, Melba J. T. Vasquez

was elected president of Division 35, and Richard Suinn was elected president of the American Psychological Association.) Sue, Bingham, Vasquez, and Suinn acted on the momentum of this historic occasion by deciding to create a national multicultural summit as a celebration of their combined presidencies. Now a biennial event, the National Multicultural Summit has been attended by as many as 1,000 participants and is an important venue for the discussion and dissemination of multicultural research.

the third son of Chinese immigrant parents. He received his Bachelor of Science degree from the University of Oregon in 1966 and his doctoral degree in clinical psychology from the University of California, Los Angeles (UCLA) in 1971. He completed his dissertation research on cognitive dissonance under Bertram Raven's guidance but soon turned his scholarly attention to mental health issues facing ethnic minorities.

Sue was an assistant professor and associate professor of psychology at the University of Washington between 1971 and 1981, professor of psychology at UCLA between 1981 and 1996, and since 1996 has been professor of psychology and Asian American Studies at the University of California, Davis. In addition to his faculty appointments in psychology, Sue has served as associate dean of the graduate division at UCLA and as the director of the Asian American Studies Program at University of California, Davis. Sue's influence on Asian American psychology and ethnic minority psychology spans a wide range with respect to scholarship, service, and public policy.

### Scholarship

Sue has made significant theoretical and empirical contributions in the areas of ethnicity and mental health, cultural competency, and effective delivery of mental health services. His first major contribution was to document treatment disparities in mental health services for ethnic minorities. In his early collaboration with Herman McKinney in the 1970s, Sue analyzed the utilization patterns of nearly 14,000 clients seen in 17 community mental health agencies serving King County in the state of Washington. They found that ethnic minority clients tended to drop out from treatment at a higher rate and to have fewer average number of sessions than White clients. Based on this research, as well as on the consensus of other Asian American mental health providers, Sue made several policy recommendations to improve services for ethnic minorities, such as training therapists to be more knowledgeable about cultural bases of mental health, to recruit and hire more ethnic minority psychologists, to develop ethnic-specific mental health service centers, and to create new therapies and services that better meet the needs of ethnic minorities. These recommendations became fundamental building blocks for increasing cultural competence in mental health service delivery.

Sue's groundbreaking studies, which suggested that inadequate services were being provided to ethnic

---

## SUE, STANLEY (1944– )

---

Stanley Sue is a pioneering scholar in the field of Asian American psychology and ethnic minority psychology. He was born in 1944 in Portland, Oregon, as

minorities, were initially challenged by the Washington State Department of Social and Health Services and Sue was asked to testify before the Washington State Senate subcommittee on mental health. After his successful defense of the scientific basis for the findings, many of Sue's policy recommendations were implemented in many areas of the country. In fact, Sue directed the training for the National Asian American Psychology Training Center in San Francisco in 1980, which was established specifically to train service providers in culturally competent practice with Asian Americans.

The early work documenting treatment disparities led Sue to pursue research on culturally competent services. In a 1987 paper, Sue and Nolan Zane proposed a theoretical model for treatment outcome based on various forms of match between therapists and clients. Sue and Zane contended that ethnic match between therapists and clients is important because ethnically matched therapists tend to have higher ascribed credibility with clients, but other factors (e.g., therapist–client match on problem conceptualization and goals, therapist behavior during the first session) contribute to achieved credibility that lead to better retention in treatment and more positive outcomes. In his 1998 paper, Sue articulated his hypotheses about three essential ingredients of cultural competency. In this paper, he argued that although *culture-specific knowledge* (e.g., making direct eye contact with an elder person would be considered disrespectful in a Chinese culture) was a necessary component, a culturally competent clinician must also demonstrate *scientific mindedness* (i.e., to treat such cultural-specific knowledge as a hypothesis rather than as a given in a particular client) and practice *dynamic sizing* (i.e., to know when to apply or not apply a particular culture-specific knowledge to assess and treat a particular client).

Finally, Sue has played a critical role in fostering cutting-edge research in Asian American psychology. He directed the National Research Center on Asian American Mental Health, a research center funded by the National Institute of Mental Health, between 1988 and 2001. Sue and his collaborators at the research center produced some of the major empirical work in Asian American mental health. For example, Sue was critically involved in the first large-scale psychiatric epidemiological study of Asian Americans in the United States, which was headed by David Takeuchi

and conducted out of the National Research Center on Asian American Mental Health in Los Angeles. This study documented population estimates for the prevalence of major mental disorders among Chinese Americans.

## Service and Advocacy

As a pioneer in the field of Asian American psychology, Sue was instrumental in creating a professional organization to provide scholarly network and public advocacy for the needs of this population. Together with his psychologist brother Derald Wing Sue and other Asian American mental health professionals in the San Francisco Bay Area, Sue founded the Asian American Psychological Association (AAPA) in 1972. In the formative years of the AAPA, Sue and other leaders sought to advocate nationally on behalf of Asian American mental health issues through the American Psychological Association (APA) boards and standing committees that were sympathetic to concerns of Asian Americans and ethnic minorities. Sue and other AAPA leaders also formed coalitions with the leading ethnic minority psychologists of the time to push the APA to move toward more diversification and inclusion.

With encouragement from Patrick Okura, the then executive assistant to the director of the National Institute of Mental Health (NIMH), Sue wrote a conference grant proposal to the NIMH to convene a national conference on the training of mental health service providers to serve Asian American communities. After 2 years of planning, the National Asian American Psychology Training Conference was held in Long Beach, California, in the summer of 1976. This historic conference was critical to the grassroots movement for Asian American psychology in gaining the momentum toward visibility and influence.

Sue's research on mental health of ethnic minorities has impacted public policy on a national scale as well. Sue has served as a task panel member for the President Carter Commission on Mental Health in 1978, planning board member for the Surgeon General's Report on Mental Health in 1999, participant in the White House Conference on Mental Health in 1999, and science editor of *Mental Health: Culture, Race, and Ethnicity* in 2001—a supplement volume to the 1999 Surgeon General's Report on Mental Health.

In recognition of his work and achievements, Sue has won numerous awards and recognitions in all areas of his work. Of note, he has received three major awards from the APA, making him one of a handful of psychologists to be awarded multiple times by the organization. Among the many prestigious awards he has garnered are the APA Distinguished Contributions to Psychology in the Public Interest Award in 1986; the APA Distinguished Contributions to Research in Public Policy, the Distinguished Contributions to Research in Ethnic Minority Psychology from the Society for the Psychological Study of Ethnic Minority Issues (APA Division 45), and the Distinguished Contribution Award from the AAPA in 1990; the Janet E. Helms Award for Mentoring and Scholarship in Psychology from Teachers College, Columbia University, in 1993; the Distinguished Contributions to the Psychological Study of Diversity from the American Association of Applied and Preventive Psychology in 1995; the Dalmas A. Taylor Award for Pioneering Leadership, Scholarship, and Aggressive Advocacy for Ethnic Minorities at the National Multicultural Summit and Conference in 1999; the APA Distinguished Contributions to Applied Research and the Society of Clinical Psychology's (APA Division 12) Stanley Sue Award—which was established to recognize a psychologist who has made distinguished contributions to the understanding of human diversity—both in 2003; the Distinguished Research Contributions to Ethnic Minorities from Section IV of the Society of Clinical Psychology (APA Division 12);

and the Davis Prize for Teaching and Scholarship from the University of California, Davis, in 2005.

## THIRD WORLD

---

Many authors concur that the *third world* is a term used to describe countries and nations who are poor, in political crisis, contending with pollution, and in debt. Berger believes these differences between developed and underdeveloped nations have also been described as a North–South conflict wherein the developed nations are the North and the underdeveloped are the South. It is assumed that the third world represents a stable set of countries, nations, and territories, but the geographic boundaries between first, second, and third world countries is vague. The *third world*, as a term, has also been used in political movements. Blauner suggests that during the anti–Vietnam War and civil rights movements, a number of organizations used *Third World* to identify themselves as liberation oriented, anticapitalist, and anticolonialist or postimperialist. Because there are many uses and connotations for the term *Third World*, this chapter attempts to clarify the origin of the term and identify how psychologists may better understand its function among individuals.

### Origination of the Third World

In 1952, Alfred Sauvy, a French sociologist and demographer, coined the term *Third World*. Originally, the term was *tiers monde*, and was used to describe the “third estate” of commoners who aspired to be similar to the first estate, or society’s wealthy and elite. Hobsbawm posits that the notion of a third estate was later used to describe nations that did not belong to either the capitalist and postcolonial nations representing the first

world or the socialist and communist nations comprising the second world. More specifically, Sachs shows that the first world represented countries that were either already industrialized as of 1945 or newly industrialized. These countries are generally described as capitalist or proto-capitalist. For instance, the representatives of the G8 (United States, England, Germany, Italy, France, Russia, Japan, and Canada) are considered the first world. The second world are either current or former communist and socialist countries and are characterized by state ownership of production, central planning, one-party rule, and economic connections with other second world countries.

In 1955, the Bandung Conference in Indonesia created the Non-Aligned Movement. During this conference, the term *Third World* became widely accepted to describe the members of the Non-Aligned Movement. The participants in the conference represented nations who considered themselves non-aligned with either the first or second world. These countries opposed colonialism and neocolonialism and were often newly emancipated from colonial powers. Representatives from countries such as China, India, Vietnam, Egypt, and Ghana agreed that they would develop economically through partnerships with each other, would nurture their own industries and infrastructure, protect and subsidize their businesses, refuse aid from foreign multinationals and countries, and limit international trade.

Although the original intent of these non-aligned countries was to become independent from first and second world hegemony, this vision of autonomy quickly evaporated. First, starting around the 1940s, global decreases in mortality rates due to such things

as the use of DDT and pharmaceutical advances contributed to a population explosion in some countries. Historically, in some countries, high fertility rates were countered by high mortality rates; but as mortality rates decreased, birth rates did not decrease. Additionally, Hobsbawm shows that the population increases were often not matched with economic development in some third world countries.

Second, Sachs argues that by isolating themselves to global developments in technology, industry, and trade, some third world countries were unable to sustain themselves economically. To help their economies, some countries turned to assistance from the first and second world nations. As third world countries became less aligned and committed to each other, they became more reliant on political and economic assistance from first and second world nations. Consequently, third world countries became politically polarized and economically dependent. Chomsky shows that first and second world nations used third world countries as political proxies and sometimes increased political instability to meet political, economic, and military goals. A coup d'état, for instance, came to symbolize political instability in many third world countries, and Latin American governments were often derogatorily referred to as "Banana Republics." Additionally, many third world countries started to borrow monies, thereby increasing their foreign debt. Consequently, foreign debt came to be the single largest economic problem for many third world countries.

Third world development was often treated differently from European or Japanese postwar development. Rather than provide grants, as the Marshall Plan did for post-World War II Europe, many third world nations were given loans. The United States learned that European debt after World War I created a financial crisis that contributed to the Great Depression and indirectly to the rise of fascism and eventually World War II. But this lesson was not applied to the economic situation in many third world countries. Instead, loans were given to some third world governments that were corrupt and/or inept, and these countries incurred debts that were impossibly high and could never be repaid. For many countries, the only solutions are debt relief or forgiveness, combined with better free-trade agreements.

### The Third World and Mental Health

For psychologists and other mental health care providers, the *Third World* is often used to describe

conditions and settings of abject poverty or other settings of extreme deprivation. The term may be used to connote, even within the United States, situations of severe poverty, poor health conditions, and economic inequality. The term has moved away from describing nation-states, as originally coined. In current use, it communicates about people and situations with dire need and intervention by mental health care providers.

For mental health care providers, multiculturalists, and those interested in social justice, the Third World represents countries and those individuals who have experienced extreme deprivation. Along with economic inequalities, many of these individuals may have experienced poor treatments by these governments, such as jailing, torture, and other traumas. Comas-Diaz and Padilla believe that individuals from many Third World countries may have comorbid posttraumatic stress related to their experiences in their country of origin. Because many of these individuals are immigrants from other countries, mental health care providers need to be aware of the aggregate affects of migration, trauma, and poverty on the migrant or refugee. When working with these communities and individuals, acculturative stress related to the lack of psychological and economic resources may be especially acute. Along with being attuned to adjustment disorders, mental health care providers need to be conscious of other possible sequelae of migration from the Third World such as depression, anxiety, and posttraumatic stress.

## TOKENISM

---

Tokenism involves the symbolic involvement of a person in an organization due only to a specified or salient characteristic (e.g., gender, race/ethnicity, disability, age). It refers to a policy or practice of limited inclusion of members of a minority, underrepresented, or disadvantaged group. The presence of people placed in the role of token often leads to a misleading outward appearance of inclusive practices. The term *token* is derived from the Old English word *taken*, which means “to show.” Thus tokenism exists because inclusion of the person or group is required or expected, not because of inherent value.

Psychological research suggests that tokenism may occur when members of the underrepresented group comprise less than 15% of the total environmental organizational context they are a part of. Furthermore, when there is only a single representative of a given group in an organizational environment, he or she is considered to have what is termed *solo status*.

Historically psychological research has focused on the experiences of (White) women as they tried to achieve full participation in the workplace. However, in recent years racial and ethnic minorities, people with disabilities, gay men, lesbians, and the elderly have been increasingly the focus of research regarding the effects of tokenism in the workplace. Tokenism, or the role of one as a token, does not necessarily

indicate mistreatment or injustice. However, as a result of unfair and inequitable practices, tokenism is associated with several negative outcomes.

## Consequences

Tokenism has both individual and organizational impacts. On the individual level a person in the role of a token may feel dehumanized, stereotyped, marginalized, and depersonalized. Quality of life, mental and physical health, and potential for success in the organization may be compromised. For example, this person may begin to question his or her qualifications or abilities, and negative outcomes may result, such as pressure to conform, feelings of isolation, lowered morale, or depression. A person in the role of a token may experience a “glass ceiling” in the organization; that is, his or her success or ability to advance is limited by unseen forces because they are symbolic rather than full participants in the organization.

Token status is more likely to have negative consequences for members of groups that are lower in status or are more culturally stigmatized. Research has indicated that people who feel like tokens may experience challenges as underrepresented members of their specific social context. Three of these challenges are visibility, role encapsulation, and contrast. Visibility entails the perception that others pay a disproportionate amount of attention to people who feel like tokens and are hypervigilant concerning their actions and behaviors. Consequently, those who are in the position of token may feel they are constantly being examined or evaluated. Persons who feel like tokens in an organization may feel intensely self-conscious about how they react to their environment because of the expected and/or internalized pressure to represent their entire minority group.

Role encapsulation entails the group dynamic where a person is forced to play a role based on stereotypes of their group. For example, a racial/ethnic minority psychology faculty member may be expected to only teach classes related to multiculturalism, regardless of their area of expertise. Token status may produce negative consequences for members of traditionally underrepresented and stigmatized groups by increasing feelings of distinctiveness based on group membership, which can increase the salience of negative stereotypes or stereotypical expectancies.

The third challenge, contrast, emphasizes the majority group’s established differences between

themselves and the people who are tokens that lead to unclear and inauthentic boundaries among the groups. These boundaries, although aimed to protect the majority group members, end up causing the identified tokens in the groups to isolate themselves as a means of protection from mistreatment or expectations of mistreatment by majority members (e.g., being perceived as intelligent when other group members are perceived as uneducated).

For the organization, tokenism may negatively impact morale, lead to high rates of turnover of people from underrepresented groups, and, most pointedly, tokenism eventually may deprive the organization of the full contribution (i.e., diversity) that the individuals in the role of token might have made to the organization. Thus tokenism itself is limiting and can potentially inhibit an organization from developing and competing in a diverse and global marketplace. Of course it should be noted that practices such as tokenism are intended to prevent change from occurring and to preserve the status quo.

### Implications for Psychologists

Psychologists are specifically directed toward knowledge of tokenism to facilitate multicultural organizational development in the 2002 American Psychological Association *Guidelines on Multicultural Education, Training, Research and Organizational Change for Psychologists*. Psychologists have an ethical imperative to combat tokenism on the individual and organizational level. On the individual level psychologists can help empower clients who feel like tokens in their environments by helping the client adopt a systemic perspective on tokenism. A full range of options (leaving the organization, attempting to change the organization, adapting to the organization) can be explored. Special care should be taken so as not blame clients for their feelings (in essence, blaming the victim).

On the organization level, psychologists can serve in the role of change agents, consultants, and/or advocates. With knowledge of multicultural organizational development, psychologists can aid organizations in making substantive change. First, the psychologist can help motivate the organization to desire change based on both the benefits of change and a comprehensive evaluation of current and past discriminatory practices. Psychologists can help organizations recognize that a single individual should not be expected to represent an entire population group. Because of the increasing diversity in the population and culturally

diverse backgrounds represented in today's workforce, organizational culture may need to change to become inclusive at all levels and to be competitive in a diverse marketplace.

The development of innovative strategies that would incorporate the ideas and beliefs of all members of the group will help to ensure equality and a more inclusive environment for all involved. Although the identified tokens may overcome these negative experiences and the stereotypical beliefs of majority group members, the process can be slow.

The organization can reduce tokenism by avoiding assumptions (stereotypes) associated with the minority group. Combating stereotypes may include implementing advocacy and outreach education into institutional practices. Additionally, working to reduce the difficulties associated with token or solo status requires there be a diverse representation in the power structure of any group. Also, organizations can ensure that underrepresented groups are represented beyond a demographic or symbolic level. Beyond the issues of representation, true organizational change includes the issue of equity in outcomes (salaries, promotions, leadership opportunities).

## TRANSLATION METHODS

---

The language barrier is one of the biggest obstacles to effective cross-cultural research, testing, and counseling. Translation methods are specialized procedures

designed to make possible the communication between people who speak or read different languages. Four translation methods have been identified. The first two are oral methods: (1) simultaneous oral translation, also known as interpretation, and (2) language switching. The other two are written methods: (3) written translation, and (4) back translation. These methods are implemented in three main contexts in the field of counseling. First, translation methods are utilized to communicate with clients in the context of a clinical counseling relationship. To communicate verbally with non-English-speaking clients during intakes, assessment interviews, and early interventions, the most efficient method is the use of trained interpreters who use a simultaneous translation method also known as interpretation. For treatments, a common method utilized in an ongoing clinical situation is the oral translation method known as language switching. Second, translation methods are utilized to turn research and testing material originally conceived in one language into another language. The most researched translation method for research and testing is the method known as back translation. Third, translation methods are utilized in counseling agencies and other institutions to translate written materials from one language into another. The consensus is that institutional forms, such as informed consent, HIPAA (Health Insurance Portability and Accountability Act), and other written materials, need to be translated by a professional translator.

## Historical Background

Translation methods grew out of the intercultural and cross-cultural communication needs that expanded toward the second half of the 20th century in the United States. The services of professional translators and interpreters became common in a variety of settings, including business, industry, health care, law, and education. In the clinical counseling field, translation and interpreting was incorporated as immigration from Asia, Latin America, and Eastern European countries increased the number of clients requesting help at counseling agencies. Increases in demand for non-English-speaking counseling in the United States, coupled with a shortage of non-English-speaking counselors, have forced organizations to become responsible for offering interpreters and translators as part of their intake, assessment interviewing, and short-term intervention services. The high expense of hiring professional interpreters has led to the need to incorporate the utilization of paraprofessional foreign language interpreters. The

increased need of translators continues to pose challenges. Few counseling organizations hire certified interpreters, and many erroneously utilize the services of bilingual staff not trained in translation methods or mental health, or the relatives of the clients requesting services. The American Counseling Association's ethical guidelines of 2005 include the new recommendation of providing interpreters or translators for non-English-speaking clients.

The initial attention paid to the role of language and translation in long-term clinical counseling comes from the psychodynamic tradition. In the 1970s, authors argued that accessing certain material is more difficult for people who have had an early encoding in a different language and that bilingual clients have different experiences of self according to which language they use. Recent contributions to the psychodynamic literature posit that bilinguals may have two different language codes and that each language system may be related to different experiences of the self. Treatment proposals include analyzing the dual experience of language by utilizing a translation method called language switching.

The method of back translation used in research and testing has its origins in the fields of health and nursing, which, in turn, influenced the field of psychiatry. Most assessment and research instruments were developed originally in English. Researchers and practitioners in other parts of the world who wish to use certain instruments use the back translation method. In 1990, the National Institutes of Health in the United States enacted a policy requiring the inclusion of minorities in study populations, which prompted translation of research instruments. Though there continue to be challenges in the attempts to standardize back translation principles for tests, questionnaires, and assessment instruments, translation of instruments from one language to another for cross-cultural use has become a widespread activity.

## Interpretation

Bilingual capabilities are not sufficient for providing interpreting services. The ability to speak a second language is sometimes confused with the ability to interpret. However, when language match cannot be ensured, the services of an interpreter are required. Simultaneous translation, also known as interpretation, is a professional activity. In the counseling field, both professional and paraprofessional interpreters are used in a variety of clinical situations, including psychiatric,

substance abuse, forensic, and other assessments and in short-term interventions. According to scant literature on the subject, working with foreign language interpreters is an acceptable, beneficial, and common use of bilingual paraprofessionals who can be trained to deliver appropriate, ethical services provided that each party in this three-way communication process can agree on some basic procedures. When counselors are trained to work with an interpreter, they learn how to ask one question at a time, speak in short sentences, and wait for the interpreter to finish sentences. When interpreters are trained in the field of counseling, they learn to be the transparent mediator between the client and the counselor. The interpreter's role needs to be inconspicuous and provide a direct and simultaneous translation of counselor's and client's words, without analyzing, summarizing, or explaining but rather directly and literally translating utterances. The interpreter, thus, needs to be able to translate what has been heard, without correcting, improving, or changing the client's words. It is recommended that the interpreter use first person when translating, as if he or she were speaking for him- or herself, instead of in third person.

Counselors need to develop alliances with interpreters and learn to communicate effectively with an interpreter in the room. For example, clients and counselors can be encouraged to speak directly to each other, engaging in direct eye contact with each other. For optimal effectiveness in the use of interpreters, time should be allowed for pre-session orientation between the counselor, the interpreter, and the client to clarify the roles in the process, to orient the client, and to answer any questions the clients may have regarding confidentiality or any other aspect of the process of engaging in a session with the presence of an interpreter.

With non-mental health paraprofessionals used as interpreters or with professional interpreters who do not have the clinical mental health background, prior meetings between the counselor and the interpreter are needed to discuss areas of possible difficulty, identify specialized vocabulary that might be needed during the session, and voice ethical concerns.

### **Language Switching**

With few exceptions, long-term counseling relationships between non-English-speaking clients and English-only-speaking counselors is difficult, if not impossible, to sustain. It is possible, however, for the

monolingual counselor to work with bilingual clients provided that they have the capabilities to engage in an intimate conversation in English. It is in these treatment situations that the method of language switching has been proposed as a form of oral translation. Clients who have had encoding in more than one language often have different ways of accessing affective reactions depending on which language they are using. Researchers recommend assessing the language acquisition history and current usage to find out what experiences are associated when each language is encoded and how the languages are currently used. Language switching is a method whereby a client can be encouraged to say something in English first and then switch to say the same thing in the language in which the experience was encoded, even if the counselor cannot understand it. The counselor can then ask about affect, memory, or other differences that are elicited by the use of two languages. Bilingual clients' language switching can serve to disclose traumatic or emotionally charged content that may not be accessible otherwise. Also, language switching offers the opportunity to explore clients' different sense of self in both languages and the different cognitive and affective components of each.

### **Written Translation**

Written translation is a professional occupation that requires native written fluency in the target language and the ability to render a cultural adaptation of the original text into a new version that is coherent, well written, and culturally accurate. Bilingual capabilities are not sufficient credentials for providing written translation services, and oral proficiency in one language does not guarantee written proficiency. Professional translators are writers who can effectively render the message of the original text with accurate style and terminology. Bilingual individuals may speak two languages fluently but may not necessarily know how to move information between the two in writing. When counseling organizations do not use professional translators for their written material, translation mistakes can ensue that may be costly, embarrassing, and disrespectful.

### **Back Translation**

Back translation is used when researchers use testing instruments with populations in non-English-speaking

countries or with linguistic or cultural groups that differ from the population used to develop the instruments. Back translation methods are also used to translate instruments into American Sign Language. The goal of the back translation method is to ensure that the original and the translated versions of the instrument are semantically and culturally equivalent. The translation of concepts across cultures poses challenges to the researcher interested in adapting instruments for use in languages other than the original. There is evidence that suggests that an inadequate translation and cultural adaptation of an instrument can result in one that is less reliable or valid than the original version. The most widely used translation model in research consists of a series of repeated forward translation and back translation exercises conducted by a team of bilingual translators blind to the previous translations. This process continues until the back translation is considered to reflect congruence of meaning between the original version and the translated one. A challenge to the researcher is to ensure that the assessment tools are equivalent across groups, that the questions capture the same constructs, and that the instruments are culturally equivalent in both languages. Care needs to be taken to ensure that a systematic method of translation renders content and conceptual equivalency, in addition to semantic equivalency. To achieve cross-cultural adaptation more fully, researchers may also rely on committees of expert panels, field testing, and pilot studies, in addition to back translation.

## TRANSRACIAL ADOPTION

---

Transracial adoption refers to the placement of children with parents who are racially and ethnically different from the children. The practice of transracial adoption has a long and complex history. Throughout the history of transracial adoption, it has been referred to as *interracial adoption* or *cross-cultural adoption*. Traditionally, the term *transracial adoption* referred to the adoption of Black children by White parents in the United States. However, over time, all transracial placements where the adoptive parents and children were racially different were included in this terminology. Thus, various forms of domestic and international adoption (also referred to as *intercountry adoption*) can result in transracial adoption when the children and parents differ racially and ethnically (e.g., Korean children adopted by White parents). Transracial adoption is the most visible form of adoption due to the phenotypic or visible differences between the adoptive parents and children. In the United States and abroad, the vast majority of transracial adoptions have consisted of White parents adopting children of color or children who are racial/ethnic minorities in the United States. Some estimates suggest that approximately 8% of all adoptions are transracial in nature.

## History

Transracial adoption has a long and complex history. Poverty, war, oppression, cultural practices, and social taboos have frequently been core explanations for the rise of both domestic and international adoptions. Although world history may have a sparse sprinkling of stories of transracial placements, transracial adoption was not formally practiced on a large scale until after World War II, and those transracial adoptions were primarily international in nature. Despite the common adoption strategy of matching (e.g., religion, race, appearance) used in adoption practice at that time, domestic transracial adoption began to serve as an option for couples looking to adopt during the 1960s.

## Domestic Transracial Adoption

The earliest recorded transracial adoption took place in 1948 in Minnesota. Transracial adoptions on a larger scale took place later; some of the earliest cases of domestic transracial adoption placed American Indian children into White families as a result of the Indian Adoption Project that took place between 1958 and 1967. This project was intended to place these children with families from the dominant culture and away from Indian reservations, and it led to 395 American Indian children being placed in what were both domestic and international transracial placements. Criticisms of this practice ensued, resulting in the 1978 passage of the Indian Child Welfare Act, which made adoption by non-native Americans very difficult.

To begin to move the large numbers of orphaned African American children out of institutional settings (i.e., orphanages), domestic transracial adoption was instituted, challenging a widespread belief that race-matching was vital to the formation of family bonds. However, the extreme difficulty in placing African American children in adoptive homes prior to transracial adoption led to the designation of African American children available for adoption as meeting the criteria for “special needs” at that time. The Open Door Society, “Operation Brown Baby” in Oregon, Minnesota’s Parents to Adopt Minority Children, and the Council on Adoptable Children advocated for transracial placements, and more than 2,500 domestic transracial placements of African American children with Caucasian families took place in 1970. Within a few years, however, criticisms of transracial adoption were levied by prominent adoption

advocates. In 1972, the National Association of Black Social Workers predicted poor psychological adjustment and problematic racial identity for transracially adopted children as results of this practice that opponents referred to as “cultural genocide.” In response to their criticisms, the Child Welfare League of America reversed the changes it had made to the adoption standards and supported the perspective that same-race placements were preferable for orphaned children.

To attend to the concerns of opponents to transracial adoption, empirical research studies were conducted to assess the psychological adjustment and racial identity development of the children who had been transracially adopted. Using Black, transracially adopted children and comparing them to their non-adopted peers, the first studies (as well as many subsequent studies) used combinations of measures, interviews, parent reports, and teacher reports to conclude that the transracially adopted children were generally adjusting as well as their nonadopted peers. Estimates suggest that 70% to 80% of transracial adoptees were adjusting as well as their nonadopted peers. These findings were complicated by reports of increased referral rates and disproportionate ratios of adopted persons in psychiatric treatment. More recent research explains the higher rates of psychological problems among adoptees in comparison with their nonadopted peers as due to a skewed distribution where the majority of adoptees were adjusting well and in the middle of the distribution, but at the extremes, there were substantially higher rates of adoptees than nonadoptees.

After a series of studies was conducted to disprove the criticisms of transracial adoptions, legislation was passed that allowed resurgence in transracial adoption placements (e.g., the Multiethnic Placement Act of 1994). Subsequent research has worked to clarify these concerns, and legislation (e.g., Interethnic Placement Act of 1996) has prevented restrictions in adoptive placements based on these concerns. The Multiethnic Placement Act of 1994, sponsored by Senator Howard Metzenbaum (D-Ohio), banned agencies that received federal funding from denying or delaying transracial placements of orphans on the basis of race alone. However, this act did allow the use of race as one of several factors that could be considered in foster and adoptive placements. In 1996, this law was revised in the Interethnic Placement Act. This law prohibited the consideration of race in any

way when federally funded agencies made placement decisions.

### International Transracial Adoption

International adoption was utilized to care for orphans from war-torn Europe after World War II, but the Korean War in the 1950s led to a more widespread and visible form of international adoption. In practice, South Korean orphans were placed with White American adoptive parents, thus constituting some of the earliest transracial placements. Since that time, international adoptions have taken place from a wide array of countries. In 2005, 7,906 visas were issued to orphans adopted from China to the United States. Other countries from which children have been adopted by U.S. citizens include Guatemala, South Korea, Kazakhstan, Ethiopia, India, Haiti, and Colombia. International adoption has also faced criticism and opposition with references to it serving as a clear example of American imperialism and as a result of colonialism. Despite these criticisms and changes in the availability of children and policies for international adoption, international transracial adoption continues to be an increasingly popular option for couples seeking infants for adoption. Historically, as the availability of White infants in the United States decreased due to the increased social acceptability of single-parenthood and pregnancy out of wedlock, families seeking to adopt have turned to international adoption. Poverty, wars, political crises, population control policies, and social taboos in countries around the world have continued to provide children for adoption. In 2005, 21,968 children were adopted internationally and the vast majority of those adoptions would also be considered transracial in nature.

### Transracial Adoption and Counseling

Transracial adoption and counseling have a brief and inconsistent history. Recent issues of *The Counseling Psychologist* have given brief attention to counseling issues for transracial adoptees, but no systematic study of clinical issues, counseling skills or techniques, or counseling process has focused on transracial adoptees. Adoption advocates and more counselors and psychologists have drawn attention to the need for “adoption sensitive” or “adoption competent” counseling skills. Nationally, several U.S. states (e.g., Oregon, New Jersey, Connecticut, New York, and

Washington) have developed certificate programs in therapy with adoptive families. Despite the dearth of studies on the counseling process with adoptive families, research, anecdotal reports, and case studies reflect that common concerns for transracial adoptees tend to center on racial and ethnic identity.

### Identity Development for Transracial Adoptees

Given that one of the chief concerns of opponents to transracial adoption is racial/ethnic identity, identity issues among transracial adoptees must be explored. The research studies that examined racial/ethnic identity for transracial adoptees have generally concluded that they identify with their racial/ethnic group differently than do nonadopted individuals from their same racial/ethnic background. However, that different identification has not been systematically or empirically demonstrated to be associated with psychological maladjustment or self-esteem difficulties.

One model to address these issues was created by Amanda L. Baden and Robbie J. Steward and is called the cultural-racial identity model. The cultural-racial identity model serves as a framework for understanding and attending to racial and cultural differences among parents and children and by considering the impact that the experiences and the attitudes of parents, peers, extended family, social support networks, and the larger community have on identity development. This model accounts for transracial adoptees’ shifting affiliation or connection with their adoptive parents’ culture (e.g., often White, American, middle-class culture), their birth culture (e.g., the culture into which they were born), people from their parents’ racial group (e.g., often White Americans), and people from their own racial/ethnic background. Transracial adoptees navigate the cultures and racial/ethnic groups with which they are familiar and those with which they want to become more familiar, adept, and at ease. In essence, the process of developing an identity around culture and race is often a primary task for transracial adoptees throughout their lives.

## TRIMBLE, JOSEPH E. (1938– )

---

Joseph E. Trimble is a pioneer and distinguished psychologist widely known for his work in cultural diversity, multicultural counseling, and issues related to culture and psychology. He has published extensively in peer review journals, books, and technical reports and has an extensive list of presentations at professional conferences. His contributions to service are extensive, and he is heavily sought out for his expertise and eloquence as a speaker. He has received numerous awards and citations for his career achievements and contributions.

Trimble is a social psychologist who is located at the Center for Cross-Cultural Research, Department of Psychology, at Western Washington University in Bellingham, Washington. He is also a research associate at the University of Colorado Health Sciences

Center and the National Center for American Indian and Alaska Native Mental Health Research. He is a scholar and adjunct professor of psychology at the Tri-Ethnic Center for Prevention Research at Colorado State University. Trimble received his B.A. degree from Waynesburg College in 1961, with concentrations in psychology, natural science, English literature, and French. He obtained an M.A. in general psychology from the University of New Hampshire in 1965, and in 1969, he received his Ph.D. in social psychology at the University of Oklahoma. His concentration was in interdisciplinary studies in psychology and sociology at the Institute of Group Relations.

### Awards

Trimble's extensive list of awards, honors, and fellowships include the Allen L. Edwards Lecturer Fellowship at the University of Washington; Radcliffe Fellow at Radcliffe Institute for Advanced Study at Harvard University; Peace and Social Justice Award given by the American Psychological Association's (APA) Division of Peace Psychology; Distinguished Psychologist Award in 2002, awarded by the Washington State Psychological Association; Janet E. Helms Award for Mentoring and Scholarship in Professional Psychology at Teachers College, Columbia University; Paul J. Olscamp Outstanding Faculty Research Award, Western Washington University; Lifetime Achievement Award from Division 45 (Society for the Psychological Study of Ethnic Minority Issues) of the APA; Excellence in Teaching Award from the Western Washington University; election to Fellow status from the APA; and Fellow of the National Science Foundation. These awards were based on Trimble's scholarly contributions together with his extensive service contributions within psychological associations, university settings, and committees that set policy in, and direction for, the field of psychology.

### Service

Among his numerous service contributions, Trimble served as president of Division 45 of the APA; chaired the Committee on Ethnic Minority Recruitment, Retention and Training Task Force Textbook Guidelines Initiative of the APA; served as a member of the APA Council of Representatives; and chaired numerous committees of the APA related to ethnic

minority issues and Native Americans. As a university professor, Trimble has served on various committees of governance and issues related to ethnic minorities, and he has taught courses in psychology, human services, and occasionally in curriculum theory and instruction. To date, he has chaired over 30 master's theses and several doctoral dissertations, and he has served on more than 30 additional master's-level thesis and doctoral-level dissertation committees.

## Publications

Trimble has written 91 peer-reviewed journal articles, chapters, and monographs; 15 authored or coauthored books; and 75 technical reports. He has given more than 130 professional presentations. He has been associated with 23 different journals throughout his career as an associate editor, editorial board member, reviewer, and consulting editor. Besides his professional contributions, Trimble's personal journey in achieving these accomplishments has shaped his thinking and perspectives.

## Personal Journey

Trimble's formal training, career achievements, and significant contributions did not let Trimble sway from understanding and appreciating his cultural, ethnic, and familial roots. In a chapter he wrote for the second edition of the *Handbook of Multicultural Counseling*, he describes his personal journey as a psychologist in training and in the profession. The struggle of managing two or more cultures with polarizing perspectives is similar to that of many minority psychologists of that time and even today. On the one hand he was raised with a perspective about life that is seen as more holistic, that emphasizes cooperation and collaboration, and that integrates the interrelationships, commonalities, and interconnectedness of all factors that influence behavior. On the other hand, the field of the social sciences and the mainstream U.S. culture tend to emphasize competition over cooperation, to prefer methods of thinking that reduce factors to a few variables of importance over the interrelatedness of factors, and to view unexplainable phenomena,

such as culture and social influences, as extraneous factors of minimal importance.

The opposing perspectives in psychology generated a determination to seek out others who had similar concerns about linking culture and psychology. With the support of an Arapaho elder and his grandfather, these conflicts only motivated him to provide the scholarship and research that was missing in the field demonstrating the connection and the importance of examining context that includes culture and ethnicity. As a true pioneer, Trimble has paved the way for others to join and build the body of knowledge, while at the same time advocate for the perspectives of appreciating diversity and integrating culture and ethnicity within the field of psychology.

## UNIVERSALISM

---

Universalism is defined as the principle that a given value, behavior, theory, or treatment will be the same across all groups independent of culture, race, ethnicity, gender, and other social identities. This principle has been a core philosophical assumption within the fields of counseling, psychology, medicine, and many other social sciences. This foundational tenet has maintained a stronghold on theories, research, and practice within the counseling profession. In addition to being a core belief within counseling, universalism has also become one of the central philosophical perspectives in defining multiculturalism.

### **Core Belief Within the Counseling Field**

Historically, the dominant view within counseling has been that theories and practices are to be viewed as universal hypotheses that require empirical examination to test their veracity, meaningfulness, and effectiveness. Developmental theories examining moral and cognitive development as well as counseling theories such as behaviorism and Gestalt are just a few examples of theories that purport to address the concerns and realities of all individuals. Even though attention to individual differences has always been a core belief within the counseling profession, the universal assumptions within many of these theories were not rigorously challenged until multicultural

scholars identified them as being culturally insensitive and not inclusive of alternative worldviews. This etic point of view suggests that it is possible and productive to fully understand all aspects of psychology, and even a particular culture, from a universal standpoint. Examples of such universal assumptions include how we define what is “normal,” what is “effective” counseling, and who is a “good” client. Another universal assumption is the belief that all disorders occur in all cultures and present in similar ways.

Fields such as counseling, psychiatry, and assessment have all experienced the effects of universal assumptions and biases that have led to discussions, sometimes controversial, about their effects on theories, diagnosis, norm groups, and standardized testing. The ultimate effect of universalism on theories and practice can be ethnocentric, androcentric, and even counterproductive when human complexity and diversity are not actively incorporated.

Cultural relativism is an alternative approach to understanding the behaviors, beliefs, and perspectives of others. Rather than presume that the experiences, beliefs, and developmental processes are the same for all others, examining specific cultural and individual realities help to inform this alternative perspective. This belief does not presume that having a global understanding has no value but rather that universal and cultural realities can be mutually considered and applied to bridge cultural, political, and other group differences and further our understanding of human behavior.

## Universalism and Cultural Differences Within Multicultural Counseling

Within multicultural counseling, various philosophical assumptions about multicultural perspectives in counseling have been used to organize the assumptions and strategies used for multicultural counseling and training. Descriptions of those diverse perspectives vary depending on an author's point of view. A universalistic or etic definition of multiculturalism encourages a transcendental perspective that is grounded in human commonalities. This universal approach tends to emphasize within-group differences as being greater than between-group differences. In other words, differences within groups (like unique aspects of American Indians) are more significant than differences between groups (like African Americans and Latino/a Americans). Some proponents of the universal perspective have expressed concern that focusing on cultural differences can lead to stereotyping, overgeneralization of group perspectives, or a type of cultural determinism that takes away both individually unique and universal aspects of a person. Universalism within the multicultural movement has a different perspective than the universal perspective present in the larger field of psychology. Individuals within the multicultural movement who embrace universalism do not deny culture but rather choose to focus on the human bond that connects all individuals. They believe many aspects of psychology, such as emotion, may be universally present in all cultures, but they manifest differently across cultures.

Most other perspectives could be classified within the cultural differences point of view, which is typically viewed as an alternative to universalism. The cultural difference approach, whether it focuses specifically on race or a broader understanding of difference (e.g., gender, sexual orientation), typically emphasizes incorporating the ideographic experiences of a particular cultural group as the basis for interpreting their behavior and offering psychological services. This emic point of view suggests that a culture's perspective is best understood from within that culture. Individuals who embrace the cultural difference perspective suggest that the universal point of view ignores the crucial realities of racism and other forms of oppression and their impact on the sociopolitical histories, power dynamics, and identity of various cultural groups. Issues of cultural bias and avoidance of cultural realities may be more likely to occur in a perspective that does not specifically value and embrace

cultural differences as core. The cultural difference point of view does not deny that there are universal realities that connect individuals but rather chooses to view such universal connection as less central to understanding individuals who have been historically underserved and misunderstood by the counseling profession.

## Future Directions

The universal versus cultural difference discussion is inevitably dichotomous. Although these diverse perspectives acknowledge and embrace some aspects of the other beliefs, they approach the issue of human difference from unique standpoints. Within the multicultural field there has been some discussion of the need to reconceptualize such dualistic thinking away from either/or perspectives and embrace a more unifying dialectic point of view.

Many multicultural scholars articulate the need to combine the universal and cultural relativistic perspectives to counteract their weaknesses and accentuate their strengths. The possibility of integrating a universal and inclusive perspective that honors the various social identities experienced by all (e.g., gender, social class, sexual orientation, religion) with a race-based approach that honors the unique history of race and racism in the United States would be an alternative approach that moves beyond the either/or dichotomy of universal versus culture specific. Discussions about universal and cultural relativism represent an important and ongoing conversation that is occurring within the multicultural counseling field.

Universalism will continue to be a core belief within psychology as a whole and within the specific field of multicultural counseling as counselors struggle to fully understand and explain human beings and their behaviors. However, the continued existence of cultural differences as well as cultural biases will create the need for a cultural differences perspective. Undoubtedly, such definitions will evolve as counselors attempt to appreciate and integrate the complexity of individual, cultural, and universal perspectives, and it is likely that universalism and the similarities that link human beings will remain a significant point of view.

## VISIBLE RACIAL/ETHNIC GROUPS

---

*Visible racial/ethnic groups* is a euphemism for racial/ethnic classification in the counseling profession when discussing American racial/ethnic groups that are non-Caucasian or not of European descent. This terminology, coined by Janet E. Helms and Donelda A. Cook, for African, Latino/a, Asian and Pacific Islander, and Native/Indigenous Americans, is an alternative to the term *racial/ethnic minority groups*. Identifying visible racial/ethnic groups as “minorities” in research and counseling implicitly compares these groups to Caucasians/European Americans as the standard, thereby disempowering them. Additionally, the term *minorities* connotes subordinate social status. The use of the terms *minority* for visible racial/ethnic groups and *majority* for Caucasian/European Americans reinforces the existing racial power differences in societal relations in the United States.

The term *visible racial/ethnic groups* signifies two aspects of American racial socialization of peoples of African, Asian, Latin, and Indigenous North American descent. The first aspect focuses on common cultural characteristics, norms, values, attitudes, and behaviors that stem from cultures of origin and are transmitted across generations. For example, cultures of Africa, Asia, Latin America, and Indigenous North America typically stress the importance of the collective society, emphasizing interdependence and connectedness. Secondly, the term *visible racial/ethnic groups* recognizes the ways in which the aforementioned groups have been subject to unequal social, economic, legal, and political power in American society, based on

visible racial characteristics, such as skin color, facial features, and native language.

### Implications of Racial/Ethnic Labels

#### **Professional Mandate**

The *Publication Manual of the American Psychological Association, Fifth Edition*, calls for the appropriate identification of research participants and clientele by specifying major demographic characteristics such as sex, age, and race/ethnicity. Language for racial/ethnic designations changes over time, and members of designated racial/ethnic groups perceive some terms negatively. It is recommended that racial/ethnic designations reflect the preferred nomenclature of the groups discussed. It is important to use terminology that empowers racial/ethnic groups in their collective social identities, as well as in their psychological well-being.

#### **Historical Evolution of Racial/Ethnic Labeling**

During the early 20th century, psychological research (i.e., intelligence research) and counseling practice recognized racial differences by comparing Caucasians with non-Caucasians (typically Black Americans) and interpreting any differences between groups against Caucasians as the standard or normative group. Thus, non-Caucasian groups were labeled deviant or deficient when found to differ from Caucasians as research participants and as counseling clientele.

As the representation of visible racial/ethnic group counselors and psychologists increased in the 1960s, they began to confront the deficit models of diversity in the profession, moving toward affirming diversity in racial/cultural identity. That is, research and practice began to examine cultural characteristics of African, Asian, Latin, and Indigenous Americans, to develop normative standards common to each racial/ethnic group. Research of within-group differences rather than between-group differences was promoted. The positive aspects of each racial/cultural group were affirmed by within-racial-group research.

In the 1970s, the social and psychological influences of racial oppression on members of visible racial/ethnic groups came to the forefront in counseling research and practice. The influence of racial socialization on the counseling process examined White counselor–Black client relationships and expectations for counseling. William Cross's theory of psychological Nigrescence introduced the role of oppression as a critical factor in shaping the stages of Black racial identity, emphasizing the impact of Blacks' encounters with the White normative standard in the development of Blacks' sense of their social and psychological identities. In the 1980s and 1990s racial identity theory in research and practice was expanded to all racial/ethnic groups. Racial identity theories are concerned with how individuals abandon the effects of oppression (as either oppressed or the oppressor) and develop respectful and equitable attitudes toward their own racial group and other racial groups.

Research in the 21st century recognizes race/ethnicity in the United States as a social construction rather than a biological entity, with racial/ethnic designations reflecting how society perceives individuals and how individuals come to perceive themselves due to racial socialization. Racial classifications are not precise measures: Self-designations of race or racial designations by others (i.e., researchers, counselors) are based on societally defined categories and societal racial positive and negative stereotypes.

The term *visible racial/ethnic groups* is an attempt to recognize the differential societal status of the socio-racial classifications for Blacks/African Americans, Asian and Pacific Islanders, Latinos/as, and Native/Indigenous Americans. This terminology also retains the cultural heritage transmissions of the respective ethnic groups.

## VONTRESS, CLEMMONT EYVIND (1929– )

---

Clemmont Eyvind Vontress, American counselor educator and psychologist, is recognized generally as a pioneer in cross-cultural counseling. He first used the

concept of cross-cultural counseling in a speech at the University of Virginia in 1968. He has contributed to the literature on the impact of culture on counseling, existential psychotherapy, and traditional healing in Africa for nearly 5 decades. Early in his career, he focused his attention on problems that Anglo-Americans encountered in counseling Black Americans. After researching the national culture and its subsystems in the United States, Vontress examined how cultural differences affect the entire counseling process, regardless of the client's background. Today, he is considered one of the leading writers on culture and counseling. During the past 2 decades, Vontress has contributed significantly to the literature on traditional healing in Africa and its implications for counseling culturally different clients in the West. Living and learning in a primarily racially segregated society in the first half of the 20th century, he was influenced significantly by the ethos of the civil rights movement in the United States. His strong feelings about human rights and the equality of people were evident in his writings during the latter half of the 20th century. His concerns about counseling Blacks in segregated and integrated school systems culminated in *Counseling Negroes*, the first book to explore the topic. By the 1970s, race and culture were dominant themes in the counseling field. Vontress was in the forefront of the increasing number of counselor educators who wrote and spoke often at national, state, and local professional conventions about cultural, ethnic, and racial differences as barriers in the counseling enterprise. It was in the late 1970s, 1980s, and the 1990s that Vontress began to explicate existentialism, the philosophy underpinning his personal approach to counseling. In 1979 he outlined his philosophical approach to counseling in the article "Cross-Cultural Counseling: An Existential Approach." In writing and speaking about how existential philosophy can be used as a therapeutic modality, Vontress established himself in the counseling field as a leading advocate of existential philosophy in counseling in general and cross-cultural counseling in particular. After several research and study trips to West Africa where he met with traditional healers and some of their clients, he began to explain in his writings and discourses how spirituality is necessarily a part of the counseling process. He came to respect the efficacy of traditional healing and viewed African healers as partners in the helping profession and in helping people, especially those in developing countries. Starting in

the 1990s, his keen interest in and respect for traditional healing have been reflected in his writings.

## Background

Vontress was born in Alvaton, Kentucky, in 1929, the year the stock market crashed and the Great Depression began. After graduating from high school in Bowling Green, Kentucky, he attended and graduated in 1952 from Kentucky State University with a B.A. in French and English. Shortly after enrolling in graduate school at the University of Iowa, he was drafted into the U.S. Army and spent a tour of duty in Hammelburg, Germany. While there, he made several trips to Paris. On one of these occasions, he saw and heard Jean-Paul Sartre and Simone de Beauvoir holding forth in a brasserie. This was his first exposure to existentialism. Later, he would read *Existentialism: With or Without God*, by Catholic priest Francis J. Lescoe. He indicated that one of his graduate students, Morris L. Jackson, steered him in the direction of existentialism by recommending Lescoe's book.

Having grown up in legally segregated Kentucky, in Europe he was astonished to see the racial harmony there and wondered why it could not exist in the United States. His experiences abroad would change his outlook on the human condition. He became increasingly focused and filled with new meaning in life and was more optimistic about his future. He was determined to achieve in spite of the social conditions that hindered his development and that of his fellows. He completed the M.S. degree in 1956 and the Ph.D. in 1965 in counseling at Indiana University in Bloomington, Indiana. As a graduate student, he studied the counseling theories of Carl Rogers and E. G. Williamson, well-known counseling theorists at the time. It was while working on his Ph.D. that Vontress had the opportunity to engage Carl Rogers in a question-and-answer dialogue. The study of counseling and human behavior was, in part, due to the influence of his mother from whom he learned by example empathy, striving for perfection, perseverance, quietude, stoic endurance, and unselfishness. The experiences in Europe changed his outlook on life from pessimism to progressive optimism, which manifested itself as an inner driving force that spurred him to achieve. People who entered into his life space recognized that life seemed to have a mission for him. Upon listening to one of his Ph.D. professors' lectures about people being culturally deprived, culturally disadvantaged, or

disadvantaged, he decided to focus aspects of his writing on culture and its impact on counseling. Throughout his professional career, Vontress has been an English teacher, high school counselor, counselor educator, and psychologist.

### Cross-Cultural Counseling

Culture as an important factor in the counseling relationship always has been a centerpiece of Vontress's writings. He considered culture to be the sum total of a people's belief and procedures for negotiating environments sustaining and affecting their existence. He maintains that it is simultaneously visible and invisible, conscious and unconscious, cognitive and affective. A major shift in his understanding of culture took place when he espoused existential philosophy. Within this philosophical framework, he viewed culture as encompassing five concentric and intersecting cultures: (1) universal, (2) ecological, (3) national, (4) regional, and (5) racio-ethnic. He posited that the universal culture was the most foundational because it influenced all others.

People are more alike than they are different and are similar and dissimilar at the same time. Vontress views cross-cultural counseling as a human-to-human encounter. Therefore, culture, per se, is not necessarily an impediment in a counseling relationship. The key factor contributing to an effective counseling relationship is the ability of the counselor to accept the client as a co-equal human being. The essential therapeutic ingredient is the humanness of the counselor and his or her ability to connect with others in need of help. Vontress recommends that counselors resist the temptation to focus on cultural differences and focus instead on human similarities. In the human-to-human encounter, counselors need to understand their own humanness and that of their clients who have come to them for understanding and resolution of concerns.

Cross-cultural counseling has been the primary focus of Vontress's life work. It was in the late 1960s at an American Personnel and Guidance (now the American Counseling Association) meeting that he presented a paper titled "Cultural Barriers in the Counseling Relationship." It was later published under the same title. In it, Vontress introduced the concept "cross-cultural counseling." Counseling becomes cross-cultural whenever the counselor is unable to understand the humanness of the client and tries to engage from a culturally different perspective. Cultural,

racial, ethnic, and other visible differences become impediments to effective intervention. Because differences are perceived as well as real, a cross-cultural dyad may consist of almost any two individuals who fail to recognize their common humanity.

### Existential Cross-Cultural Counseling

Existentialism is a philosophy that advocates that people recognize the reality of human existence. Basic to this reality is the continuous movement toward death. Frequent national and international travel caused Vontress to develop a global perspective of humankind. It also contributed to his development of an existential approach to cross-cultural counseling. According to him, existentialism develops and enhances our relationships with ourselves, others, nature, and spirituality. He recommends that counselors use the Socratic dialogue as the basic technique in cross-cultural counseling. Vontress's existential cross-cultural counseling approach was influenced and inspired by Ludwig Binswanger. Central to existential cross-cultural counseling is an understanding of the existential concepts *Umwelt* (physical world), *Mitwelt* (public world), *Eigenwelt* (private world), and *Uberwelt* (spiritual world). It is also important to understand that ideally the worlds interact harmoniously to ensure a balanced existence for human beings. Vontress's existential cross-cultural counseling approach requires the individual to fully grasp the concepts of existentialism and his or her significance at different stages in the counseling relationship.

### Traditional Healing

Vontress's study of traditional healing in Africa was simultaneously a study of his historical roots. The visits to Africa provided a deeper understanding of himself and his own humanity. The paradigm shift in his worldview was made evident by his interest to document in writing his newly found understanding of humanity. It was in 1991 that he wrote his first article on Africa. Vontress continues to write about existential cross-cultural counseling and traditional healing in Africa, and he nurtures his understanding of humanity by interacting authentically with colleagues and by mentoring countless students, many of whom come from Africa.

---

## WHITE, JOSEPH L. (1932– )

---

Joseph L. White, born in 1932 in Lincoln, Nebraska, is a well-known African American professor, psychologist, activist, scholar, researcher, consultant, educator, and mentor who revolutionized traditional European American psychology by setting the stage and foundation for what is now known as cross-cultural psychology and multicultural counseling. White received his undergraduate and master's degrees in psychology in 1954 and 1958 from San Francisco State University and graduated with a Ph.D. in clinical psychology and developmental psychology in 1961 from Michigan State University. White has held positions of psychologist, dean, director, assistant vice chancellor, and professor at institutions such as Washington University; California State University, Long Beach; San Francisco State University; and most recently the University of California, Irvine (professor emeritus of psychology and psychiatry). As a luminary in the cross-cultural psychology field, White—respectfully and endearingly known as “Joe,” “The Godfather,” and the “Father of Black Psychology”—has been challenging theories of psychology, academics, clinical agencies, organizations such as the American Psychological Association (APA), and numerous university and psychology boards for more than 40 years.

White graduated during the groundswell of the 1960s civil rights movement and quickly emerged as a leader of social justice, diversity, and equality in psychology and in the community. White's formal education, talent, intellect, and social and political connectedness brought him into the company of

individuals such as Malcolm X, Stokely Carmichael, Eldridge Cleaver, and other members of the Black Panthers and brought him appointments to work with California Governor Edmund G. Brown, San Francisco Mayor Willie Brown, and presidential candidate Robert F. Kennedy.

In September 1968, White and a small group of African American psychologists founded the Association of Black Psychologists (ABPsi) at the San Francisco meeting of the APA. White's initial steps to revolutionize psychology began in 1968 when he and other members of the fledgling ABPsi confronted members of the APA and the convention planning committee regarding the absence of Black programming in psychology. Their truth was reality—that the struggles, strengths, science, practice, and psychology of Black Americans were not reflected in the largest organization of scientist-practitioners educating America on psychology, research, and therapy. Disheartened, angry, and driven by scholarship, White was determined to shift the paradigm of thinking on how psychology defines ethnic minority individuals. Until the 1960s, Black and other minority individuals were conceptualized according to European American and Western standards of living and psychology. In 1970, White published his seminal and groundbreaking article “Toward a Black Psychology” in *Ebony* magazine. His article provided validation to African Americans and ethnic minorities from a Black American perspective and inspired individuals to question psychology and ask questions such as “How does traditional psychology address the mental health needs of ethnic minority individuals?”

White's pioneering work propelled individuals, such as Derald Wing Sue and Stanley Sue, to form other

ethnic psychological organizations such as the Asian American Psychological Association, the National Latina/o Psychological Association, and the Society of Indian Psychologists in the following years. ABPsi served as the forerunner of more ethnic organizations and of the creation of Division 45 (Society for the Psychological Study of Ethnic Minority Issues). White's trailblazing actions gave support to others committed to social justice who also went on to become prominent leaders in the field of multicultural psychology (Wade Nobles, Allen Ivey, Stanley Sue, Derald Wing Sue, Thomas Parham, and William Parham to name a few).

White continued to expand traditional American psychology toward a cross-cultural psychology as evident in his commitment to improving the mental health treatment for people of color. Again, his scholarship flourished in his writing and cowriting of several editions of *The Psychology of Blacks: An African American Perspective*, *The Troubled Adolescent*, *Black Man Emerging: Facing the Past and Seizing a Future in America*, and, most recently, *Black Fathers: An Invisible Presence in America*, all of which have been instrumental in the creation and current discourse of cross-cultural psychology and the fourth force of multicultural psychology. Underlying White's contributions to psychology are concepts including the historical realities of people enduring the physical and psychological pains of racism, discrimination, and prejudice. He has taught that throughout history in psychology, the poor, the minority, and the non-White have endured the emotional pains resulting from being compared with their European American/White counterparts and being conceptualized as inferior. White's writings and teachings clearly shifted the paradigm of thinking in bringing awareness to counseling and in the application of differing cultural conceptualizations needed into a psychology developed and normed primarily for middle-class European Americans. Furthermore, the core of and development of Black psychology and much of White's theoretical and practical concepts have focused on human strengths, highlighting resilience, "healing in the broken places," and recognizing the positive aspects of one's life course rather than the dysfunction and pathology that one has experienced. Thus, Black psychology needs to be acknowledged as a psychology originally rooted as a psychology of strengths and positive psychology in its theoretical underpinnings and practical application.

White's contributions to cross-cultural psychology and multicultural psychology are not limited solely to

his writings and activism. Over the past 4 decades, he has taught, inspired, advised, guided, mentored, and spiritually touched hundreds of individuals, encouraging them to be change agents, to seek social justice, and to make a difference for one individual, which, in turn, will make the larger society a smaller, more manageable place. White truly believes if people make a difference in one person's life and they then make a difference in five people's lives, then this world will be a better place. White's consummate mentoring has been witnessed and experienced by many and has earned him the status of "The Conductor of the Freedom Train," a supportive pipeline for undergraduates in the tracks of aspiring to earn a Ph.D. in psychology. White created opportunities for minority and ethnic students and other students alike to experience the mentorship from beginning to end, as undergraduates to doctoral graduates in psychology. He carefully crafted such opportunities to ensure success and support in pursuit of graduate school in psychology. His pipeline and "Freedom Train" started at the California State and University of California systems and has continued for decades now with students earning Ph.D.s from reputable institutions including Southern Illinois University, Carbondale; University of Maryland, College Park; University of Missouri, Columbia; Washington State University, Pullman; and more. White's teaching abilities, his presence at conferences, his ability to connect with diverse people, and his genuine care to increase the numbers of ethnic minorities who pursue Ph.D.s in psychology are precisely why it has been believed that White has mentored more Ph.D. students in psychology than any other individual in the field, with the majority being individuals from diverse racial-cultural backgrounds.

White has gone beyond making *psychology* a household word and has encouraged individuals to apply their psychology education and diversity knowledge to other fields. Administratively, White worked toward increasing the numbers of ethnic minorities entering college. In addition to mentoring graduate students through counseling/clinical/school/child psychology programs, he was involved in the founding of the Educational Opportunities Program (EOP) at California State University, Long Beach (which led to the development of EOP systemwide). Additionally, White was active in both Head Start and Upward Bound programs in Southern California. In addition to diversifying the educational system, White also was

appointed by Governor Brown to serve as chair of the Psychology Examining Committee, State of California, where he fought to integrate and represent the interests of diverse people in the statewide system, in clinical work, supervision, on the Exam for Professional Practice in Psychology, and toward the overall practice of psychology. White has served on numerous committees to create diversity on campuses and has done more than his share in applying his psychological knowledge to diversify the American educational system and psychology. Along the way, he has guided professionals in law, government, business, higher education, political administration, academia, private practice, and medicine with regard to minority mental health. Each generation taught by White continues to advance the field of ethnic minority psychology in some capacity.

Those who know White know of his legacy and pioneering work in the field of Black psychology and multicultural counseling. As reflected in his history, White has had a lifetime of achievements that have advanced the field of ethnic minority psychology. White's several articles and books have served as roots and will continue to serve as the branches to an evolving cross-cultural psychology. White's contributions have been acknowledged through numerous awards, including the 2000 Lifetime Achievement Award from APA Division 45 (Society for the Study of Ethnic Minority Issues), the 2007 Henry Tomes Award for Distinguished Contributions to the Advancement of Ethnic Minority Psychology, and a 2007 honorary doctorate from the University of Minnesota, Twin Cities, for his life contributions to the field of psychology. He was also chosen as one of psychology's senior men of color at the National Multicultural Conference and Summit in 2001.

As a 75-year-old African American licensed clinical psychologist and professor emeritus in America, White has reached all walks of life, people, races, sexual orientations, and color in leading by example and incorporating cross-cultural psychology in his daily life. White's contributions have, without doubt, advanced ethnic minority and cross-cultural psychology as we know it today; his impact has been profound.

## WHITE AMERICANS

---

The identity of White Americans can be described along a number of dimensions. Perhaps the most basic is the statistical portrait derived from numerical data as compiled by the U.S. Census Bureau; however, a more nuanced understanding of this group emerges from consideration of their history, culture, and social location.

### White Americans by the Numbers

White Americans are one of the five racial designations defined by the U.S. government, the others being Black/African American, Asian, Native American/Alaskan Native, Native Hawaiian/Pacific Islander (and Other). Whites are defined by the U.S. government as comprising people of European, Middle Eastern, or North African descent. The U.S. Census conducted in 2000 found that 77.1% of the American population indicated that they were White, alone or in combination with another race, with 75.1%

reporting that they were White only. Whites also had the opportunity to indicate their family ancestry, the most commonly reported being German (with 15.2% of the total population), followed by Irish (10.8%) and English (8.7%). With regard to place of residence, Whites are distributed fairly evenly throughout the United States, with the largest total numbers of Whites living in the South (34%) and the Midwest (25%) relative to the West (21%) and the Northeast (20%). The highest concentrations of Whites can be found, however, in the populations of the Midwest (85%) and the Northeast (79%).

### Sociopolitical Location

In terms of their social, political, and economic standing, White Americans are the dominant racial group in the United States. The United States has had White presidents and vice presidents exclusively, and as of the November 2006 elections, Whites held approximately 94% of seats in the U.S. Senate and 83% percent of those in the House of Representatives. With fewer than 10 exceptions throughout history, all elected governors of all 50 states have been White. Whites occupy the overwhelming preponderance of corporate executive positions, serving as chief executive officers at about 495 of the 500 largest corporations as represented by *Fortune Magazine* in 2006. White people are overrepresented in every powerful and highly paid profession: Overwhelmingly, American lawyers, judges, physicians, bankers, college professors, and journalists are White. The vast majority of American wealth resides in White hands, as documented by Meizhu Lui and her colleagues in their 2006 book *The Color of Wealth*. For every dollar of wealth owned by a White family, people of color own less than a dime. Family median net worth (i.e., assets minus debts) provides another way of looking at this disparity. According to the Federal Reserve Bank, the median net worth for White American families in 2001 was \$120,900, whereas for people of color it was \$17,100. In short, in nearly every walk of life, the lists of the wealthiest, the most powerful, and the most influential feature a preponderance of White Americans.

### The Origins of Whiteness

Another way of understanding White Americans involves the origins of Whiteness itself as a collective group identity. Race in general has been declared a

biological myth by bodies such as the American Association of Anthropology; rather, racial groupings are understood to be socially constructed, historically contingent identities that arise from a particular confluence of social, cultural, political, and/or economic forces. More specifically, the notion of Whiteness as a meaningful way to categorize human beings is a fairly recent development that did not exist at the time the first European settlers ventured onto this continent. The first colonists, therefore, would likely have called themselves English, Dutch, German, or perhaps Christian rather than White. As described by such historians as Howard Zinn, the socioeconomic forces that initiated the creation of Whiteness in the 1700s derived from the emergence of one of the most important economic engines of the new American nation: the transatlantic slave trade. Not only were the profits to be made from the importation and sales of African people considerable, the developing plantation system relied completely upon slave labor. In response to the necessity of justifying these practices, Whiteness materialized as a new group identity that collectively privileged the new American owning class by establishing a racial hierarchy in which Whites could claim superiority. Whiteness, therefore, provided a rationale for the buying and selling of Africans and their children, their subsequent lifelong enslavement, and the appropriation of all profits from their labor.

Africans were not the only people to find that Whiteness—or more specifically, the occupation of a social location outside and beneath it—bore important consequences in their lives. Conquered people of color throughout Central and South America and the Caribbean lost their land and resources to White colonialists, while Asians in the United States saw their wealth-building opportunities legislated away by White lawmakers. Such legislation had its foundation in the Naturalization Law of 1790, which stated that only “a free White person” was eligible for American citizenship. In the century that followed, Asians of every ethnicity filed suits in state and federal courts claiming that they had the right to be considered White and thus were among those allowed to own property and be protected by law. These included, for example, Takao Ozawa, who emigrated from Japan in the late 1800s, attended the University of California, and raised a family in Hawai‘i where he worked for an American company. He appealed the repeated denials of his naturalization requests all the way to the Supreme Court, where, in 1922, he was denied a final

time for the stated reason that he was not Caucasian. Finally, in the 1940s, racist laws such as the Chinese Exclusion Act of 1882 and the Alien Land Law of 1913 were repealed.

By law, therefore, Whiteness constituted the legally sanctioned platform for social and economic dominance in America well into the 20th century. White Americans' historical control of political power, property ownership, and wealth creation, in addition to all the other rights of full citizenship, sheds light on the contemporary concentration of wealth and power in White American hands. Moreover, it is from this historical context that Whiteness derives meaning; for this reason, psychologist Ruth Frankenburg has conceptualized Whiteness itself as an artifact of sociocultural dominance production.

### The Culture of White Americans

Many White Americans would be surprised by the idea that they have a culture. The notion of culture is often associated in the minds of Whites with people of color and the ways in which their ethnic traditions, food, and music are seen as different or exotic. In fact, White Americans do have cultural traditions and norms, even though they are largely invisible as such to Whites themselves. This invisibility derives from the fact that Whites tend to see White culture not as a culture at all but as "just the way things are"—as the standards, customs, and values that describe the essential human experience. White culture, then, gains power through its invisibility, in that it becomes the standard against which all others are judged.

The terms *White culture* and *Eurocentric culture* have been used to describe the culture of White Americans and the worldview according to how they live and perceive reality. Accordingly, the word *Eurocentrism* refers to the tendency to order and understand reality according to the tenets, beliefs, and values of White/Eurocentric culture. Psychologist Judith Katz has explicated the components of White culture, which begin with the value of individualism, as opposed to prioritizing collective or community well-being. In keeping with this value, the individual is understood to be the primary social unit, autonomy is highly valued, and individuals are expected to master the environment and exercise control over the circumstances of their lives. Closely related is the value placed upon competition: All situations can be understood as win/lose propositions, and winning is

all-important. Status is accorded to individuals on an economic basis; money and property ownership are important symbols of status, along with titles and credentials. Communication is characterized by direct eye contact, limited emotional expressiveness, and little physical contact. Whites' sense of time is characterized by a future orientation and delay of gratification; time is viewed as a commodity and strict adherence to schedules is valued. Family structure is typically patriarchal, with the male as the traditional head of the nuclear family unit and the female subordinate to him. Beauty ideals for women are based on White physical characteristics (e.g., light skin, blue eyes, blonde hair) along with a thin body and youthful appearance; men are understood to be attractive primarily on the basis of their economic status and sociopolitical power. Musical and artistic aesthetics are derived from European models, and accepted histories are based on the perspective of Europeans who colonized the North American continent. Christian religion is foundational to White American culture, with most holidays deriving from either Christianity or White accounts of North American history.

Psychologist Derald Wing Sue has written about the culture of White Americans, their worldview, and ethnocentric monoculturalism. Ethnocentric monoculturalism refers to (a) the conviction that one's own culture is superior to any other; (b) a sense of entitlement to promulgate one's own beliefs, values, and traditions at the expense of others; and (c) the sociopolitical power to do so. Cultures are not, in and of themselves, either bad or good, and all cultures tend to privilege their own beliefs over others; therefore, it is the latter of these aspects—power—that is the key to ethnocentric monoculturalism and what makes it harmful to outgroups. In the United States, this means that groups other than White Americans, and those whose cultures and worldviews differ from Whites, are often seen as inferior, deviant, alien, and incapable, even if exotic and interesting. The fact that power resides almost exclusively with White Americans means that this negative evaluation damages the life opportunities and well-being of people of color in a White-dominated culture.

Another construct that helps illuminate the operations of Whiteness and White culture in America is hegemony. Hegemony refers to the capacity for powerful groups to maintain dominance not only through institutional, political, economic, and/or military displays of power but also through their

ability to shape cultural norms, ideals, systems of understanding, and conceptions of “common sense” in a way that supports their dominance. According to the Italian political theorist Antonio Gramsci, hegemony functions so that dominant groups exercise power from within subordinated people themselves, in that subordinated people internalize ideas and structures that define the dominant group’s power as natural and preordained. The culture of White Americans, then, can be said to be hegemonic in the United States in that many of the tenets of White culture have a natural, “of course” quality to them. Celebrations of the “rugged individual,” the symbolic display of personal purchasing power, and beauty pageant contestants of various races whose features correspond to White beauty ideals are unremarkable, taken-for-granted features of American life. Along these lines, author Toni Morrison has noted that the phrase “White Americans” itself has a redundant quality; the word *American* contains notions of Whiteness within it.

### White Americans and Privilege

Open commentary by White Americans regarding Whiteness has been infrequent, although Black scholars such as W. E. B. Du Bois have written influentially about Whiteness since before the turn of the 20th century. One of the best-known White expositors of Whiteness and its privileges in recent decades is Peggy McIntosh. In her Wellesley College working paper, first published in the late 1980s, McIntosh explored her identity as a White American and the unconscious privileges associated with it, calling it “an invisible knapsack” of assets and advantages that she carried with her into every situation. For example, McIntosh observed that, as a White woman, she nearly always had the opportunity to be interviewed and evaluated by people of her own race, that history told her that people of her race created civilization as she knew it, and that bandages and other products were made to match her skin tone. McIntosh also explored the personal and moral ramifications of allowing oneself to become aware of White privilege, noting that such awareness had direct implications regarding social justice and meritocracy: If certain people acquire unearned advantages simply by being White, then this is not a society where everyone gets what she or he deserves, and Whites who acknowledge their privilege must also acknowledge that any

success that they have enjoyed has been furthered because of it.

### Marked White Americans

As mentioned, the hegemonic nature of Whiteness in the United States means that Whiteness is, for the most part, unmarked. In other words, anything that does not correspond to White cultural ideals *is* marked as discrepant—as different, ethnic, foreign, or unusual—but Whiteness itself goes unnamed as the accepted standard according to which “differentness” is judged. One group of White Americans, however, occupies a social location slightly outside the unmarked heart of White American culture and therefore requires a label to indicate their outsider status: poor Whites, variously called White trash, trailer trash, rednecks, or hillbillies. Anthropologist John Hartigan has discussed the meaning inherent in the name-calling directed toward poor White Americans. Specifically, the fact that the “Otherness” of poor Whites requires demarcation points to the classist and racist underpinnings of White American culture. Hartigan also discussed the various shades of meaning among these labels. *Redneck* is a label that poor or rural Whites sometimes embrace, in that it conveys a defiant attitude in the face of mainstream social rejection, whereas *white trash* is an identity that no poor White wants to own, in that it corresponds to the nadir of the class spectrum and conveys the lowest point of social contempt. *Hillbilly*, on the other hand, has more specific regional connotations and encompasses the complexity of the Appalachian mountain experience: an identifiable cultural heritage of music, food, art, and love of the land, experienced within a context of shaming poverty and social isolation.

### Antiracist White Americans

One of the ways that White culture maintains its hegemonic dominance is by “erasing” White antiracist thought from history. This silence supports the impression that Whiteness has always been an accepted part of American life; moreover, those White Americans who wish to question or challenge White hegemony are left with no models of how such a thing might be done. In fact, there have always been White Americans who comprehend Whiteness and the corresponding oppression of people who are not White and who oppose the oppression outright. For

example, Thomas Paine is widely studied by American schoolchildren who learn about his influential pamphlet *Common Sense*, which advocated the emerging American Revolution against the British. What is not as frequently mentioned is that he was also emphatically opposed to slavery and wrote tracts on the slave trade that were certainly read by influential White slave masters of the day such as Thomas Jefferson and George Washington. Radical pre-Civil War abolitionists such as William Lloyd Garrison receive scant, if any, acknowledgment, while John Brown, who was hanged in 1859 for treason after attempting to instigate antislavery insurrections, is cast by history as a zealot. History instead presents White Americans with Abraham Lincoln as the Great Emancipator, a man who was politically neutral on slavery although personally opposed to it. In a letter to the *New York Tribune* in 1862, Lincoln stated that his priority was saving the Union and if he could save it without freeing any slaves, he would do so. This trend continues to the present day; White antiracists such as Robert Jensen, Judith Katz, Tim Wise, Jeff Hitchcock, and David Roediger are virtually unknown in mainstream White American culture or scholarship.

### Changing Demographics: White Americans in the Future

Since the 1990 U.S. Census, the White population has grown more slowly than the population as a whole, having increased by 5.9% as compared with the growth of 13.2% for the U.S. population as a whole. This pattern of slowing growth has led to the widely accepted view that by approximately 2050, Whites will no longer be the single most populous racial group. It remains to be seen how these changing numbers will impact the social location of White Americans or their awareness of it.

## WHITE PRIVILEGE

White privilege is the concept that European Americans benefit from specific advantages—denied to people of color—solely because of their nonminority status. These are unearned benefits derived not from merit, and these benefits are often taken for granted, if even acknowledged at all. White privilege generally refers to White, male, Anglo-Saxon, middle to upper class, heterosexual, able-bodied individuals.

The concept of White privilege has been evident in discussions of prejudice for some time, but Peg McIntosh articulated it in a way that was able to reach European American counseling students and scholars of all backgrounds. McIntosh, a feminist author writing in the area of male privilege, began to speculate, not about how she was oppressed as a woman, but whether she herself was privileged due to her status as a White person. She used the analogy of a backpack filled with unearned privileges that White persons are given at birth. Her work was seminal and formed much of the subsequent discussions on this topic.

White privilege is best understood when examined in the context of power and oppression. Individuals as

well as groups of people can be the victims of classism, sexism, racism, and other forms of oppression. Multicultural competency, a cornerstone of the contemporary counseling paradigm, involves integrating this understanding into practice. However, to achieve this end, it is important for researchers and practitioners to grasp a firm understanding of the dynamics of oppression and its underlying structural components.

Oppression denotes a feeling of being weighed down and kept down by an unnecessary or unjust use of power: Oppression exists symbiotically with power. For oppression to be present, there has to be a stratified system of power differential among people in a society. That is, one person or one group needs to be on top or in a position of power, while another person or group of people is subjugated or kept in a position without power, or at least in a position without as much power as the other group. An integral aspect in the examination of the dynamics of oppression and White privilege is the often overlooked notion that people benefit from oppression without even realizing they are doing so. Many privileged members of the group with power in society do not want to think that they are living their lives in a manner that is oppressing anyone, yet every day they directly and indirectly benefit from the dynamics of oppression.

These dynamics of oppression continue to exist in society because it is difficult to enact systemic change when people are comfortable where they are in their current state of existence. The transaction of empowerment requires a power reallocation; that is, for change to occur, the people with privilege have to surrender some degree of their power. Historically, examinations of oppression have focused on the victims. However, to best understand White privilege, there needs to be an honest and thorough examination of the people who are benefiting from this power, with an emphasis on how it is highly advantageous for them to maintain their power and privilege.

### **Tripartite Model**

The transformation of this definition of racism can be conceptualized by James Jones's tripartite model of contemporary racism, and this model is quite helpful in illustrating the manifestations of White privilege in society. Three levels of racism (i.e., individual, institutional, cultural) comprise this model. The first level, individual racism, can be defined as any action or attitude—conscious or unconscious, intentional or

unintentional—that subordinates a person or group because of their race. While hate crimes and other highly visible overt acts fall into this category, individual racism also includes the beliefs and behaviors of well-intentioned people who are unaware that their attitudes and actions may oppress people of color.

The second level, institutional racism, resides in the organizations and institutions of society. Institutional racism is defined as any organizational practice or policy in business, government, schools, churches, courts, and law enforcement agencies that is enacted to unfairly subjugate persons of color, while allowing other groups to profit from these policies and procedures. The third level of racism in the tripartite model is cultural racism, which is the individual and institutional expression of the superiority of one group's cultural heritage over that of another. Cultural racism can be conceptualized as the superordinate umbrella that influences and permits both the levels of individual and institutional racism to exist and flourish.

Evidenced in each level of this model of contemporary racism, the manifestations of White privilege are often subtle, and their hegemonic nature makes them all the more powerful—and insidious. Rarely (if ever) contested, these seemingly invisible incidents of privilege allow White persons to make unlimited withdrawals from the White Privilege bank account without ever having to make deposits or even balance the checkbook.

### ***Individual Level***

White privilege at the individual level manifests itself in many forms. It may be a subtle microaggression, perhaps even an unintentional slight, which benefits a White person at the expense of a person of color. One example, from the perspective of a person of color, is the act of a White person being waited upon first even though he or she has come to the counter last.

If the White waiter takes the opportunity in an ambiguous situation to choose to wait on this White customer before the customer of color, it is difficult to discern intentionality. Perhaps the waiter legitimately didn't see the Black person enter first. Perhaps the waiter was having a bad day. Perhaps the waiter doesn't like Black people or thinks that White patrons tip better. On the other hand, if a White patron were to see another late-arriving patron waited upon first, the race-based explanation would most likely not occur to him.

However, sifting through these explanations causes a person of color to expend cognitive energy on the distinct possibility that the waiter chose to disregard societal conventions of “first come, first serve” in favor of extending an unearned privilege to a White person because of their shared racial group membership.

A microaggression is a subtle insult or small act of racism. A microaggression, such as the one in the previously mentioned example, can cause a person of color to mentally rehearse defensive scripts and actions. If the instance is brought up to a friend, colleague, or perhaps even the waiter, a person of color has to prepare to verbally defend himself against the anticipated minimization of the experience (e.g., “You’re being too sensitive and reading too much into it”). Or the person may have to defend against the flat out denial of such a race-based explanation (e.g., “The ‘60s are over. People don’t think like that any more”). Alternately, the person of color may rehearse a defensive script wherein he directly confronts the waiter about the slight, thus taking the chance that he incorrectly attributed a racially based explanation (e.g., the waiter doesn’t like Black people) when a potentially benign explanation was more accurate (e.g., the waiter didn’t see the Black person come in first).

Other examples can be seen throughout the culture of the United States. These examples include store detectives specifically following people of color when they enter a store because the store detectives believe people of color shoplift more than White people; automatic denial of loans for automobiles or homes for people of color; or even realtors who do not show homes to people of color that are in predominantly White neighborhoods. Examples such as these contribute to the physiological and psychological distress that people feel. Lack of trust underlies the anxiety and stress people may feel, and anxiety and stress contribute to increased high blood pressure, increased heart disease, and an increase in chronic health problems.

Scenarios like these can cause unnecessary stress and duress for a person of color, whether it is an actual incident occurring or just the prospect that such a situation may occur. This race-related stress can be defined as the race-related transactions between individuals or groups and the environment that emerge from the dynamics of racism. Race-related stress can tax or exceed existing individual and collective resources or threaten well-being. Exposure to race-related stress can have psychological and physiological consequences to a member of a discriminated-against

group. The exposure to chronic forms of discrimination has been implicated in the development of several stress-related diseases prevalent in the African American community and among other persons of color.

White privilege at the individual level of racism is the ability to arrive at an explanation—benign or otherwise—to an ambiguous social interaction without legitimately considering a race-related explanation. Thus, White privilege provides White persons with a buffer from the physiological and psychological consequences of race-related stress. This buffer is not readily available to persons of color who, at some level, have to at least contemplate the possibility of a racially based explanation (e.g., skin color contributed to the waiter’s decision to wait on the White person first).

### ***Institutional Level***

At the institutional level of the tripartite model of racism, White privilege may be even more difficult to discern because the unearned benefits afforded to Whites at this level do not originate in one-on-one interactions. Rather, these privileges are embedded within societal institutions and organizations. Having had these benefits denied to them, persons of color may be acutely aware of this dynamic. However, having been raised on the dominant ideologies of rugged individualism and meritocracy, White persons may have difficulty acknowledging racism as a system that structurally benefits White persons at the expense of persons of color because doing so would threaten long-standing beliefs about society and beliefs about one’s own accomplishments.

To illustrate the nature of White privilege at the institutional level, a series of compelling questions are offered here. For example, if a White employee makes an unpopular decision at his job, does he worry that his coworkers or customers will assume that a policy such as affirmative action ensured that other more qualified candidates were passed over because his race obscured an assumed lack of ability or qualifications? Is it perceived that his merit or his skin color is the main contributor to his success (or lack thereof)?

If a White person is a defendant in court, is there a good chance that a jury of his peers shares his values or even his racial characteristics? Do these peers make implicit assumptions about his guilt or innocence based on preconceived stereotypical notions about other people who look like him? Furthermore, are

these notions based on a critical mass of real-life interactions with others who look like him, or are these notions instead based on isolated incidents or derived from movies, news reports, and other popular culture representations?

Extending beyond these issues of merit, consider assumptions that are made about the protection afforded by law enforcement agencies. Is there a systemic manner in which law enforcement is provided to members of different races? Does it take police officers a comparatively longer time to respond to 911 calls in Black neighborhoods? When teaching their adolescent son how to drive, how many White parents need to include instructions on keeping his hands in plain sight on the steering wheel in the event that he is pulled over by the police?

In contemplating the answers to these questions, the subtle and subversive nature of White privilege illustrates how institutional policies and practices unfairly subjugate persons of color, while allowing other groups to benefit. An unopened backpack of White privilege ensures that these unearned institutionally based privileges are neither acknowledged nor articulated, thus ensuring their continued receipt.

Research has shown that serious educational, occupational, economic, and health disparities exist between persons of color and White persons. In the counseling domain, there is a high rate of clients of color underutilizing mental health services and not returning for second sessions. Reasons for these include economic constraints, service access barriers, and cultural mistrust attitudes toward White counselors. When clients leave counseling early, this results in an increase in underdiagnosis and misdiagnosis, which, in turn, does not allow clients to get the help they need. In addition, psychological testing has been developed and based on the majority culture and does not always meet the needs of the client, specifically for a person of color. Testing is not always culturally sensitive, culturally appropriate, or adequate for the care of diverse clients.

Further research in the counseling literature acknowledges these disparities and highlights these institutional practices in terms of microaggressions against clients of color. These microaggressions are often perpetuated by well-intentioned White counselors, even those with extensive multicultural training. These subtle exchanges convey demeaning messages to clients of color, causing damage to the therapeutic alliance and the client's psychological well-being.

Blaming the victim, dysfunctional helping, and self-righteous assertions of being nonracist are all examples of ways that clients of color can be disserved and even victimized in therapy by White counselors. To clarify, blaming the victim involves a White counselor employing an intervention wherein the counselor assigns responsibility to the client of color for his presenting concern (e.g., depressive symptoms surrounding current unemployment). This microaggression serves to minimize or ignore the reality of White privilege, perpetuate cultural mistrust, and ignore the role of societal racism as a salient contributing factor in the presenting concern of the client of color.

Institutional practices and policies contribute to these disparities. However, because explicitly racist laws, such as Jim Crow laws, are no longer legal, it is difficult for White persons to acknowledge the systemic nature by which institutions subjugate persons of color. Instead, when disparities are observed, individual attributions are made that are congruent with majority values, and corresponding solutions (e.g., work harder, pull yourself up by the bootstraps, stop feeling sorry for yourself) serve to blame persons of color while effectively absolving institutional policies and practices of any responsibility in the matter. Thus, misattribution and denial allow institutional racism to effectively function without interruption.

### **Cultural Level**

At the cultural level of the tripartite model of racism, examples of White privilege may occur in the form of subtle societal messages that are omnipresent in society and are conveyed through myriad media (e.g., television, radio, newspapers, Internet). These messages perpetuate the belief that White culture is superior and that other cultures are subordinate. A prime example is the societal standard for beauty—blonde hair, blue eyes—that favors predominantly Caucasian characteristics. Those who do not conform to this culturally exclusive standard are not fully represented in media and popular culture and thus do not achieve the same level of beauty.

Furthermore, if an attractive African American woman is acknowledged for her beauty—beauty that deviates from this cultural norm—she may be described as an *attractive Black woman*. On the other hand, an attractive blonde-haired blue-eyed Caucasian woman may be described as an *attractive woman* rather than an *attractive White woman*. This example

of asymmetric racial marking sets the beauty of the White woman as the default standard. Her beauty does not require a specific racial designation because it is understood that this beauty (i.e., blonde-haired, blue eyed, *White*) inherently conforms to the dominant cultural standard.

### Color-Blind Approach

White privilege can be thought of as the mechanism driving the color-blind approach to race relations. A color-blind approach is the position often endorsed by members of mainstream White society wherein they purport not to see race-based differences in people. Instead, they see everybody as equals and treat them accordingly. At the surface level, this is a socially desirable perspective because it conveys the sense of a progressive belief in only one race, the human race, a belief that aligns with the perspective of encouraging people of different cultures to assimilate.

However, embracing a color-blind approach is difficult because in doing so, one neglects to acknowledge the role of power in society, insinuating that we live in a purely egalitarian society wherein the American dream is equally accessible to all members of the human race, if only they work hard enough. Furthermore, it assumes that everybody has the luxury to choose not to see differences based on color. Ignoring racial group differences can validate assumptions that minority groups share the same values as those in the majority, thus leading to maintenance of the status quo. Perpetuating this societal status quo preserves the hierarchical system of racial stratification prevalent in American society, thus denying the reality of people of color—a reality wherein racism is very real to them, despite contentions to the contrary by White persons who have the power to purport not to treat people differently based on race.

White privilege is exemplified in this ability to deny another person's reality without having to acknowledge the ramifications of doing so. This invalidation can be driven by malice, but more often than not, it is driven by naïveté or even apathy when the ramifications do not appear to directly affect White persons. Power is the benefit acquired from deciding which reality is valid, and mainstream American society affords this unearned privilege of power to White persons at the expense of persons of color.

Although the colorblind strategy may appear noble and egalitarian on the surface, it conceals the reality of

contemporary racism. Examples of overt racism represent only the tip of the racist iceberg. These examples may include the internment of people of Japanese descent living in the United States during World War II, forcing African American people to ride in the back of the bus, or dousing blankets with disease to trade to Native American people. An exclusive focus on these visible acts obscures the emergence of racism's insidious modern transformation into the invisible default standard of covert racism. Arguing against the color-blind strategy, Eduardo Bonilla-Silva reports that the United States is a racist country and due to the benefits experienced by White privilege, people continue to support racism by continuing to benefit from privilege. He also reports that seemingly innocent comments such as "I am not racist, but . . ." are more passive-aggressive in nature and continue to provide people with a forum to make racist remarks.

The use of American Indians as mascots for school and sports teams provides another poignant yet rarely acknowledged example of White privilege at the cultural level. Indian-themed mascots, such as the Cleveland Indians' Chief Wahoo, exhibit distorted versions that do not encapsulate or even accurately represent how real American Indians act or what they look like. In the absence of any (or, at best, limited) contact with real-life American Indians, mascots are the image that drives society's perceptions of who American Indians are.

White privilege is the ability to ignore the perspective of those without power or voice and to honor them on terms other than their own. Furthermore, even in the most optimistic scenario, White privilege is manifest in getting all of the facts together, listening to all relevant perspectives, and receiving overwhelming evidence and reasons to make a change. Yet White privilege grants the power to disregard all of this. White persons can rationalize their actions and prioritize other concerns (e.g., tradition, convenience, money) over the denigration of another group of people, even when the implicit becomes explicit and the hegemony of cultural racism starts to unfold. White privilege thrives in this space between.

### Extension to Other Groups

Theorists have extended the concept of group-based privilege beyond race. As stated earlier, the notion was first developed within the context of male privilege and then extended to race. Now it has been used to describe

Christian privilege. An example of Christian privilege would be the ability to assume that an individual will not be required to work on a holiday that is celebrated in your religion. It has also been extended to nondisability privilege. A graphic example of nondisability privilege is the fact that an amniocentesis test showed that you did not have Down's syndrome, so you were allowed to be born, as opposed to some people who may decide to discontinue a pregnancy because of the existence of a disability. In addition, it has been extended to heterosexual privilege. A salient example of heterosexual privilege is the fact that, if you are a heterosexual individual, you are allowed to marry and benefit from all of the legal and social positive aspects of the recognition of such a union.

## WHITE RACIAL IDENTITY DEVELOPMENT

---

White racial identity development (WRID) theory describes how White individuals develop a sense of themselves as racial beings, acknowledge the realities of structural racism and White privilege, and come to accept race as a healthy aspect of themselves and others. *Structural racism* is defined here as the policies and practices in the fabric of U.S. society that disadvantage non-White individuals; *White privilege* refers to the rights, advantages, exemptions, and/or immunities granted to White individuals that non-Whites are not provided. WRID is a specific derivation of the more general cultural/racial identity development theory. It is consistent with cultural/racial identity development theory in that it assumes that (a) people have varying levels of awareness about their group identity, (b) the level of awareness is influenced by sociopolitical factors, and (c) the level of awareness has important implications for counseling practice and training.

### Models

William Cross developed a Nigrescence model to explain the process of Black racial identity development. This Nigrescence model was later applied by Judy Katz and Allen Ivey to understand how Whites

deny their own race and the existence of structural racism. Cross's model, combined with these early investigations of how Whites understand their own race and racism, led to the development of the first WRID models.

There are several models that have been proposed to explicate WRID, and although these models differ in their description and sequence, they generally progress as follows: a minimization of oneself as a racial being and of racism; dissonance created by cross-racial experiences that challenge this naïveté; a recognition of oneself as a racial being and Whites' perpetuation of racism; and the internalization of an integrated White racial identity and comfort in cross-racial interactions. Historically, WRID models referred to *stages* of racial identity development; this term has been replaced with *statuses* to refer to the more fluid boundaries between different racial identity statuses and the dynamic processes by which individuals progress and regress between racial identity statuses.

### Helms's Model

Janet Helms's model of White racial identity development is the most researched and applied of the WRID models. Helms's model has given rise to an assessment instrument, the White Racial Identity Attitude Scale (WRIAS), to measure WRID. Helms's WRID model has received some support from psychometric scrutiny of the WRIAS. Helms's model describes six statuses that may be divided into two meta-processes: (1) abandonment of racism and (2) defining a nonracist White identity.

Lack of awareness of oneself as a racial being and obliviousness to racial issues characterize *contact status*. Here, a White person is naïve regarding the sociopolitical implications of race. During *disintegration status*, the minimization of race and racism is challenged by witnessing racial oppression or acknowledging one's own racist thoughts and behaviors. This challenges the naïveté of the previous status and creates dissonance. This dissonance may result in feelings of guilt, sadness, or anxiety and may lead a White person to avoid contact with persons of color. *Reintegration status* is marked by recourse to pro-White, antiminority attitudes to deal with the dissonance of disintegration status. One condones White supremacy and blames minorities for their own problems.

Helms's second process—defining a nonracist White identity—begins with *pseudo-independence*

*status*. When racial oppression and a racist White identity are challenged, White people make an effort to understand racial differences. The motivation for multicultural learning is present, but understanding of diversity is immature, and cross-racial interactions may be paternalistic. In *immersion/emersion status* White people search for a personally meaningful definition of Whiteness. Intentionally learning about one's contribution to racism is an important task for this status. Less emphasis is put on trying to change others as one turns inward to address personal racist beliefs and tendencies. *Autonomy status* represents an individual's acceptance of his or her Whiteness and role in racial oppression. Here, the person's reference group is multiracial and the person selects and nurtures those aspects of White culture that "feel right." Finally, the autonomous individual moves beyond intellectualization of antiracism to take action against racial oppression.

### Sue and Sue Model

Derald Wing Sue and David Sue have recently proposed a five-phase WRID model, in which individuals fluidly regress and progress across phases. This model differs from Helms's model in the way in which White individuals are theorized to address the dissonance from acknowledging racial inequality and Whites' role in racial oppression. Rather than a movement forward into a "reintegration" phase, as in Helms's model, individuals recycle back to the beginning "conformity" phase before reaching the later phases of WRID in the Sue and Sue model. The five phases of this model are discussed next.

During the *conformity phase*, a White person is highly ethnocentric, one's self-conception as a racial being is minimal, there is a conscious or unconscious belief that White culture is superior, and one professes a nonracist identity. The *dissonance phase* occurs when an individual experiences incongruence between his or her nonracist self-image and contradictory behavior. One's Whiteness and concomitant bias is acknowledged, and there is a dilemma about how to cope with this incongruence. Here, White people may return to the conformity phase or move into the *resistance and immersion phase*, characterized by a confrontation with one's own racism. In this phase, an individual becomes disillusioned to racial oppression, may reject his or her own Whiteness, and identify strongly with non-White groups. The *introspection*

*phase* is a compromise between the preceding two phases, in which one questions and reformulates what it means to be White. The person accepts his or her Whiteness and role in perpetuating racial oppression but seeks to define a new racial identity. The formation of a nonracist White identity is the hallmark of the *integrative awareness phase*. Now, an individual has an understanding of him- or herself as a racial being, appreciates diversity, is aware of oppression, and actively works to confront it.

### **Applications for Training and Counseling**

Because the majority of counseling practitioners are White, WRID scholarship has focused upon the context of understanding counselors' racial identity status in multicultural counseling and training situations. By contrast, non-White racial identity scholarship has focused upon its implications for clients rather than counselors.

From a training perspective, becoming aware of one's own White identity is an important part of multicultural counseling competency, an imperative for working with non-White client populations. Relatedly, Helms argued that White counselors with a greater degree of WRID have a greater capacity to confront and address structural racism and the racial dynamics and racial identity of their clients. Sue and Sue recommended that graduate programs assess WRID status to tailor multicultural training experiences, with the goal of making Whiteness visible and integrated into trainees' self-concept in a nonracist fashion.

Haresh Sabnani and colleagues articulated a WRID model with concomitant training goals for each racial identity status. This model incorporates aspects of the aforementioned models to create five WRID statuses: (1) pre-exposure/precontact, (2) conflict, (3) prominority/antiracism, (4) retreat into White culture, and (5) redefinition and integration. For each of these statuses, Sabnani prescribed objectives for the development of counselors' beliefs and attitudes, knowledge, and skills, with the overall goal of facilitating the counselors' movement to the next racial identity status. Their hypothesis is that counseling trainees will be differentially primed for multicultural training experiences based on their racial identity status. As Helms also argued, targeting training and educational experiences to racial identity status is critical in facilitating

White students' racial identity, their capacity to recognize their own contributions to societal racism, and their capacity to counsel non-White individuals.

WRID also has important applications to counseling. Because WRID appears to influence cross-racial interpersonal relationships, White counselors can consider how their racial identity status may influence therapeutic relationships with non-White clients. Helms advanced a complex dyadic model for this purpose; cross-referencing WRID statuses with Black racial identity statuses. The result is a description of the relational dynamic for every potential White-non-White encounter, according to each individual's racial identity development status. This understanding of dyad combinations can attenuate confusion in clinical work and may motivate White counselors to nurture their racial self-concept to maximize the efficacy of their service to non-White populations.

Research examining the impact of WRID upon aspects of the counseling and supervisory relationship has yielded mixed results. For example, Madonna Constantine found that racial microaggressions, subtly racist messages and/or behavior by White counselors with African American clients, adversely affected the therapeutic alliance in counseling. Shawn Utsey and Carol Gernat found that White trainees with less advanced racial identity statuses relied upon more primitive ego defense mechanisms in racially provocative situations within counseling and supervisory dyads. However, Alan Burkard and colleagues did not find that WRID was associated with the capacity to form a working alliance in counseling by White participants.

### **Future Directions**

Helms's WRID model has had a significant impact upon the understanding of Whites' racial identity development and in conceptualizing its impact upon counseling and supervisory dynamics. Although the WRIAS has been widely used, there has been some debate as to the correspondence between the WRIAS and Helms's White racial identity statuses. However, the Helms model and other models of racial identity development have profoundly influenced the Association for Multicultural Counseling and Development multicultural competencies and culturally informed theories of counseling. Future research could build upon the strong theoretical base of WRID to further clarify the impact of

identity status upon the working alliance and other aspects of counseling, supervision, and training.

## WORLDVIEW

---

The human psyche represents a complex constellation of activity that impacts how people perceive and respond to reality. Culture firmly impacts the human experience, and worldview is subsequently one of the most studied constructs in the field of cultural, cross-cultural, and multicultural psychology. Worldview has been defined as a person's perception of his or her relationship with the world. More specifically, worldview is a by-product of the way in which a person is socialized to perceive, think, feel, and experience the world. It attempts to make sense of life experiences that might otherwise be construed as chaotic, random, and meaningless. Worldview articulates the basic philosophical assumptions, values, and beliefs underlying culture and is expressed through its various structural or institutional manifestations. Moreover, worldview is a by-product of culture that affects, and tends to determine, behavior.

### Historical Synopsis

The construct of worldview is one of the earliest cultural variables to be integrated into psychological research, theory, and practice. Worldview represents a unifying thread in the psychological literature that suggests practices to guide culturally competent research and psychotherapy with culturally diverse communities. In 1970, J. L. White wrote the first article—"Toward a Black Psychology"—that questioned the utility of applying mainstream psychology

toward African Americans. This article, which was published in *Ebony*, argued that it was difficult—if not impossible—to understand the African American experience by using traditional psychological theories that were developed by European American psychologists to explain European American behavior. Implicit in this assertion was the position that worldview differences exist between these two groups and that a psychology that is rooted in Western philosophy could lead to conclusions that could be harmful in the scientific research, clinical diagnosis, and prescribed treatment of African Americans.

This investigation into the implications of worldview differences was advanced more broadly by D. W. Sue and his colleagues. In 1982, they published a position paper in *The Counseling Psychologist*. Ten years later (1992), Sue and his colleagues followed up with a call to the profession, which was published in the *Journal of Counseling & Development*. This body of work represented an initial step toward articulating a set of competencies that each culturally skilled psychologist should be able to wield in psychotherapy. Such competencies were organized along the dimensions of beliefs, knowledge, and skills. For the first time, the implications of worldview differences in psychotherapy were clearly delineated and therapist self-exploration was promoted. Two decades after the original position paper was published, in 2002, the American Psychological Association Council of Representatives adopted a set of guidelines on multicultural education, training, research, practice, and organizational change for psychologists. These guidelines noted that awareness of the research participant's—or client's—worldview is not sufficient to actualize cultural competence in research—or psychotherapy. Psychologists must also be aware of their own worldview and have the skills to work through worldview differences in research, training, and psychotherapy in a culturally sensitive and meaningful manner.

### Conceptualization of Worldview

Contemporary debates about the construct of worldview are focused more on how it is conceptualized and less on its utility in the field of psychology. It is widely understood that the construct of worldview can be used to understand interpersonal dynamics in a therapeutic relationship. Furthermore, some counseling psychologists have argued that therapists who work with

culturally different clients will increasingly be exposed to clients who exhibit different worldview orientations. To the extent that these views diverge, services may be viewed as unacceptable and unnecessary and may influence the underutilization of psychotherapy by various ethnic groups in our society. Given the mental health-related help-seeking disparities that plague such populations, several counseling psychologists have articulated a need for a comprehensive characterization of worldview that can be applied to psychological assessment and psychotherapy.

### Perspectives

To date, there are two primary perspectives that are driving the evolving conceptualization of worldview. The most prominent perspective is an existential approach that is rooted in cultural anthropology. Alternatively, some psychologists have tried to provide a more comprehensive articulation of worldview by investigating the depths of culture through the interrogation of various dimensions of philosophy.

### Cultural Anthropology

Traditionally, conceptions of worldview in psychology have been grounded in cultural anthropology. In 1961, F. R. Kluckhohn and F. L. Strodtbeck articulated an anthropological model of value orientations that focused on five existential categories: human nature (what is the character of human nature?), activity orientation (what is the modality of human activity?), social relationships (what is the modality of people's relationships?), person-nature (what is the relationship of people to nature?), and time orientation (what is the temporal focus of human life?). Furthermore, each existential category was thought to vary among three potential options: human nature—bad, good and bad, or good; activity orientation—being, being in becoming, or doing; social relationships—lineal/hierarchical, collateral/mutual, or individualistic; person-nature—harmony, subjugation and control, or power of nature; and time orientation—past, present, or future.

Psychologists have used this model to conceptualize various dimensions of worldview orientations and have hypothesized that the beliefs and values along each dimension are shaped by the individual's cultural context. It is important to note that researchers have also operationalized worldview according to other value dimensions such as justice beliefs, sense of

coherence, and cultural attitudes. A value-based conceptualization of worldview was the basis of several assessment instruments, including the Value Orientations Questionnaire (Green & Haymes), the Value Orientations Scale (Szapocznik & colleagues), and the Scale to Assess World View (Ibrahim & Kahn). These scales were designed to be applied to psychological research and to improve cultural competence in psychotherapy. In 1991, R. T. Carter provided a comprehensive summary of worldview studies based on this existential values conceptualization. F. A. Ibrahim, G. Roysircar-Sodowski, and H. Ohnishi later updated this review in 2001. Readers may consult these summaries for more detail.

## Philosophy

Conceptions of worldview in psychology have also been grounded in the discipline of philosophy. Psychologists such as W. C. Banks, L. James-Myers, K. K. K. Kambon, and W. A. Nobles argued that cultural phenomena—like worldview—could best be captured through the deep structure of culture. According to this conceptualization, worldview is organized into several philosophical constructs: *cosmology*—nature of the universe, *epistemology*—theory of knowledge, *ontology*—connection of psychological facts with reality, *axiology*—science of values, and *teleology*—theory that things act for an end purpose. This method of conceptualizing worldview encompasses the values-based approach, while adding a layer of complexity by including additional culturally influenced dimensions that have the capacity to deepen the breadth of the worldview literature.

Historically, the aforementioned philosophical constructs have been traced back to KMT (or Ancient Egypt) and the definitions of these constructs have been debated by philosophers such as G. Berkeley, R. Descartes, G. W. F. Hegel, M. Heidegger, D. Hume, I. Kant, J. Locke, K. Marx, and Plato, to name a few. In 2005, L. James-Myers and colleagues advanced the cosmology, epistemology, ontology, axiology, and teleology model for analyzing worldview systems. More specifically, they provided potential questions that could be used to gain insight into a person's worldview orientation. Examples of such questions included (a) How was the universe created? (b) What powers animate life and gives it form? (c) What can be accepted as truth? (d) How is knowledge obtained and transmitted? (e) What is the nature of reality?

(f) What exists in reality? (g) What are some values that can be used to guide human interactions? (h) What is the purpose of life?

Several behavioral scientists have used these philosophical dimensions of worldview to conceptualize the notion of *self* and *consciousness* for diverse ethnic groups. Additionally, several categorizations have been illustrated to delineate differences and similarities between different ethnic groups along these philosophical dimensions of worldview. A philosophically based conceptualization of worldview was the basis of several assessment instruments, including the Worldview Scale (Baldwin & Hopkins) and the Worldview Analysis Scale (Obasi, Flores, & James-Myers).

## Measuring Worldview

Although there is a multitude of psychological literature addressing the implications that worldview differences may have in conducting culturally competent psychotherapy, psychologists have been less adamant in investigating this issue in the domain of research. Within the field of psychology broadly, complex formulations of cultural phenomena often are relegated to race-based stereotypes. Whereas there are various theoretical formulations that conjecture the existence of worldview differences among various ethnic groups, there is a dearth in the amount of empirical evidence to substantiate such claims. In part, this is due to conceptual incarceration where Western science dictates what epistemology and methodology are deemed credible for uncovering such ontological relationships. In light of the imposed etic (cultural universals) methodology that is often inherent in Western science, limitations in researching cultural deep thought become inevitable when epistemological and ontological relationships rooted in various non-Western worldview orientations come into conflict with research methods that are grounded in a Western worldview.

For various reasons, this has bearing on the lack of instruments that can be used to research such theoretical formulations. When race-based instruments represent the closest alternative, researchers interested in cultural phenomena are faced with the alternative of pounding a square construct into a round hole. Research on racial constructs—such as racism, racialism, stereotypes, and race-related stress—is very much needed to address the stimulus value that physical features might have on attitude formulation or well-being. However, a racial paradigm will have

little to no utility when the researcher is interested in cultural factors that influence spiritual, psychological, and/or behavioral phenomena.

The measurement of worldview is crucial to advancing psychological theory, research, training, and practice. Specifically, worldview is an important cultural variable that has the capacity to effectively assess between- and within-group differences so that individuals can be understood within a broader ethnocultural context. Scholars also have highlighted the importance of assessing the relationship of cultural factors (e.g., worldview, acculturation, cultural identity) to other psychological variables in research studies. Moreover, investigating the influence of a client's worldview in both process and outcome variables in psychotherapy may provide important data regarding effective modes of psychotherapy for culturally diverse populations.

One characteristic of the culturally competent therapist is awareness of personal assumptions, values, and biases. An important dimension of therapist self-awareness includes understanding one's own worldview and how worldview perspectives are shaped by the processes of enculturation and socialization. A worldview assessment instrument can serve as a tool for training programs in helping graduate students become more aware of the lens through which they perceive and interpret events around them. Furthermore, worldview assessment can help therapists understand the client's perception of her or his presenting concerns. In addition to assisting in conceptualizing and assessing the problem, knowledge of the client's worldview can also aid the therapist in establishing methods and goals for psychotherapy that are consistent with the client's worldview and determining the roles the therapist might serve in the context of the therapeutic relationship.

Finally, worldview assessment is invaluable to psychological research. In 1995, A. J. Marsella and F. T. L. Leong identified several methodological problems that contribute to errors in validity in psychological research. Of importance to worldview assessment is the "error of commission." In summary, this error describes conducting psychological research on diverse ethnic groups without regard of their worldview. Not having a valid worldview assessment tool would force the researcher to make stereotypical inferences (e.g., African Americans are spiritual and communalistic people), which were not assessed in the research study, to inform their results.

Moreover, uncovering empirical differences in worldview may serve as a catalyst toward deriving much needed research methods that are obligatory for culturally competent research to be actualized.

As a result of the increased focus within psychology on providing effective services to culturally diverse populations that is informed by the research literature, and the recognition that culturally competent therapists and ethically responsible practice necessitate the assessment of worldview, researchers, trainers, and therapists are in need of measurement tools to assess worldview. To date, there are a few instruments to assess worldview orientation that are used in the psychology literature: Scale to Assess World View (Ibrahim & Kahn), Worldview Scale (Baldwin & Hopkins), and the Worldview Analysis Scale (Obasi, Flores, & James-Myers).

### **Scale to Assess World View**

The Scale to Assess World View consists of 45 items and was developed to assess individual and group beliefs, values, and assumptions regarding (a) views of human nature, (b) interpersonal relationships, (c) nature, (d) time, and (e) activity. Human nature is categorized as being either bad (3 items), good and bad (3 items), or good (3 items). The modality of an individual's relationships is categorized as being lineal-hierarchical (3 items), collateral-mutual (3 items), or individualistic (3 items). The relationship of people to nature is categorized as being in harmony (3 items), subjugation to control (3 items), or power of nature (3 items). The temporal focus of human life is categorized into the past (3 items), present (3 items), or future (3 items). Finally, the modality of human activity is categorized as being (3 items), being-in-becoming (3 items), or doing (3 items). Each item is rated on a 5-point Likert scale ranging from *strongly agree* (5) to *strongly disagree* (1). Responses to each item are trichotomized into "no," "neutral," or "yes." A factor analysis was conducted on the Scale to Assess World View and a four-factor solution was reported. These factors were named Optimistic, Traditional, Here and Now, and Pessimistic.

### **Worldview Scale**

The Worldview Scale (WVS) consists of 37 items assessing three broad philosophical-conceptual orientations of African and European worldview: (1) orientation toward nature, (2) orientation toward the

physical and the nonphysical/metaphysical realms, and (3) orientation toward other human beings. Additionally, items are included that assess the six bipolar conceptual components of harmony versus antagonism toward nature, spiritualism versus materialism, collectivism versus individualism, strong versus weak religious orientation, interdependence versus separateness, and humanism versus racism. Part I of the WVS consists of 24 items to which participants respond using a 4-point Likert scale ranging from *strongly agree* (4) to *strongly disagree* (1). In part I, 15 items are positively worded for the African worldview, and 9 items are positively worded for the European worldview. Part II consists of 9 items in a forced-choice format that alternates randomly from an African worldview response set to a European worldview response set. The WVS score is computed based on the total scale score; high scores correspond to an African worldview orientation, and low scores correspond to a European worldview orientation.

### **Worldview Analysis Scale**

The Worldview Analysis Scale is a 55-item questionnaire based on the philosophical dimensions of cosmology, epistemology, ontology, axiology, and teleology. These philosophical dimensions serve as a theoretical framework to operationalize measurable dimensions of worldview, such as perceptions of the universe, spirituality, immortality, communalism, knowledge of self, reality, reason, and indigenous value systems. Individual perceptions of these dimensions exist in the fabric of culture and are believed to influence cognitions, decisions, and behaviors. Factor analysis confirmed a seven-factor structure that included Materialistic Universe, Tangible Realism, Communalism, Indigenous Values, Knowledge of Self, Spiritual Immortality, and Spiritualism. The Worldview Analysis Scale hypothesizes several assumptions with regard to worldview assessment.

1. Worldview is a schema that is used to establish meaning consistent with a person's cultural framework.
2. Each culture possesses both universal and particular dimensions of worldview that are similar to and different from other cultures; thus, the measured dimensions should be able to differentiate between-group and within-group similarities and differences.

3. Cultures are constantly in contact with other cultures. Through these interactions, dimensions of worldview can be either borrowed and transformed in a meaningful fashion or rejected altogether.
4. Worldview is a construct that has the capacity to go beyond superficial race-based models to explore cultural phenomena.

### **Future Directions**

Historically, the majority of people of color (African American, Asian American, Native American, Mexican American, etc.) residing in the United States in need of some type of psychological intervention do not seek professional psychological help for their personal dilemmas. Of those who seek therapeutic assistance, an estimated 50% or more prematurely discontinue treatment after the initial session. Factors cited as reasons for this premature termination include traditional psychological paradigms that reflect the worldview of the dominant culture, diagnosis and treatment by a culturally different therapist, differential expectations between clients and their therapists, and lack of resources and lack of availability of services.

People of color are more likely to rely on traditional support networks (e.g., relatives, spiritual advisors, community organizations, and friends) rather than professional psychological services. This growing body of scientific literature consistently identifies common implications (e.g., diagnosis and treatment of the culturally different, differential expectations, and lack of resources in culturally diverse communities) that the field of psychology must address to improve therapeutic practice with diverse groups. Furthermore, these studies hypothesized that factors such as worldview, values associated with the counseling process, and cultural differences between the counselor and client can negatively impact an individual's willingness to seek professional psychological services.

In addition to the cross-cultural/multicultural discourse, it is imperative to look at the impact that worldview can have on designing empirically supported treatment modalities and training competent service providers to administer such interventions. Specifically, it is important to understand the factors that influence worldview and how differences are manifested between and within ethnic groups. For example, which dimensions of worldview predict counselor preferences, treatment modality preferences,

conceptualizations of health, help-seeking attitudes and behaviors, and so on? Are culture-specific treatments needed to address worldview differences, or are adjustments to current treatment modalities sufficient? It is anticipated that the construct of worldview will continue to influence the future of psychotherapy while solid empirical evidence continues to accumulate in this area of research.

## XENOPHOBIA

---

*Xenophobia* is derived from the terms *phobos* (meaning “fear”) and *xenos* (“strangers”). Thus, *xenophobia* is defined as fear of strangers or of the unknown or of anything that is different. The fears are unwarranted and triggered by unfounded beliefs and generalizations. These fears sometimes incite hostile behavior and attitudes toward the unknown target.

Some scholars suggest that xenophobia is at the root of racism such that individuals see themselves as part of a superior racial ingroup of similar individuals and see other people as part of an inferior outgroup. The outgroup members are perceived as physically and psychologically dissimilar. Thus, prejudiced attitudes and discrimination toward the outgroup member are by-products of a xenophobic climate. Expressed preferences for ingroup familiarities are problematic and reinforce intolerance in a supposedly pluralistic society. In most societies, there are individuals who are socially, culturally, or otherwise different from the majority.

Xenophobia can lead to either overt discrimination or subtle exclusion of certain individuals. This exclusion is also problematic. Persons who present an unbiased attitude but act in subtle ways that reflect implicit biases regarding race are characterized as aversive racists. The subtlety is in justifying the racist behavior based on some factor other than race. Beyond racism, xenophobia is believed to underlie heterosexism or homophobia. These irrational and irreconcilable fears of human beings based on sexual behavior and

practices are also based on gross overgeneralizations and misunderstanding.

Xenophobia is important in the context of counseling in that practitioners and clients are atypically matched by race, gender, sexual orientation, nationality, or a number of fixed factors. Xenophobia potentially contributes to racial microaggressions, subtle verbal and nonverbal communications that demean others as a function of their membership in some stereotyped group. On an implicit level, subtle behavior negatively affects therapeutic experiences and may contribute to the underuse of professional mental health services by certain groups.

People are believed to naturally categorize themselves, preferring similar others and minimizing those who are different. Although this process allows individuals to reduce complex human characteristics to simplified categories, the side effect is demeaning attitudes and behavior toward underrepresented persons across multiple contexts.

## ACADEMIC ACHIEVEMENT, NATURE AND USE OF

---

Academic achievement is axiomatic to career development processes. In people's lives, academic choices, barriers, or opportunities occur early and frequently, and they have a pervasive and lasting influence on career development. For example, a middle school student's choice of or opportunity for educational curricula limits or broadens the student's subsequent opportunity for learning experiences; a high school graduate's postsecondary educational opportunity and choice opens some occupational fields and closes others.

Academic achievement has been defined in a seemingly infinite number of ways, and some definitions are more valid, useful, and less harmful than others. In defining academic achievement, there are three salient dimensions to consider: equity, development, and meaning.

### **Equity**

Academic achievement is the main means of social mobility for people outside the mainstream of the U.S., Western, and increasingly global socioeconomic system. Yet barriers to academic achievement remain, and these barriers perpetuate the chronic achievement gaps evident in the United States and other countries. These achievement gaps produce continuing social and economic inequity and stratification. Many authors writing in the career development field have made the point that much of career development theory,

research, and practice has little use or meaning for those outside the mainstream of the U.S. socioeconomic system. That is, because many people outside the mainstream have limited opportunity—including limited opportunity-to-learn—they have no choice; and choice is frequently an explicit or implicit assumption in career research, theory, and practice.

Thus, defining academic achievement is an educational, career development, professional, ethical, social, economic, and political issue. Any definition of academic achievement that does not take into account many students' lack of opportunity-to-learn serves to perpetuate inequity. For example, in the late 1980s, several U.S. states rewarded and punished schools based on students' average scores on basic skills tests. Students in more wealthy schools had higher scores than students in poorer schools where there was less access to a quality curriculum and quality instruction. In the mid-1990s, this perpetuation of inequity was recognized, and states moved to a system based on students' degrees of improvement on basic skills tests. This current system, however, is not without fault, and no definition of academic achievement is perfect.

### **Development**

Academic achievement is naturally developmental and hierarchical. One developmental educational milestone opens opportunities for the next academic achievement endeavor. Thus, any definition of achievement must take into account the developmental nature of academic achievement. Paying attention to developmental

phenomena helps counselors and educators focus on students' and clients' past and future learning experiences in a dynamic way. A developmental perspective helps professionals see academic achievement choices, opportunities, and barriers through an equity and cultural-experiential lens.

### Meaning

The meaningfulness of academic achievement definitions, measures, or indicators is related to the equity dimension and the developmental dimension. Some developmental accomplishments have more meaning and bearing on subsequent achievement than others. If achievement outcomes have some functional meaning in terms of educational, social, and economic advancement, they are meaningful. Governments and educational institutions, however, have historically bestowed high levels of meaning on particular academic achievement outcomes that have dubious functional meaning (e.g., scores on tests with limited validity, invalid college admissions criteria).

### A Positive Example

The following is an example of a definition of academic achievement that accounts for the equity, development, and meaning dimensions: The National Center for Transforming School Counseling (NCTSC) is a component of the foundation The Education Trust. The Education Trust focuses on educational reform, educational equity issues, and closing achievement gaps. One goal of the NCTSC is for all students to graduate from high school college ready and work ready—using one intensive high school curriculum. Current school counselor training done by the NCTSC focuses on transcript analysis, with particular attention to the academic intensity of courses students complete across their middle and high school careers. Based on students' course-taking patterns, they are placed into categories representing degrees of *behind*, *on target*, or *advanced* (toward college ready and work ready). This definition of academic achievement in high school is meaningful because longitudinal national research has shown that the strongest mutable determiner of postsecondary educational success is the curriculum that students experience in middle and high school. This definition is developmental in focus, and it also takes equity issues (e.g., opportunity for an

intensive curriculum, institutional barriers, high school curriculum tracking practices) into account.

## ACHIEVEMENT, APTITUDE, AND ABILITY TESTS

---

Many psychologists use labels such as *achievement test*, *aptitude test*, and *ability test* imprecisely, and nonpsychologists use them as synonyms. This lack of precision is understandable because in actual practice, tests bearing these labels often appear to be quite similar and are used for similar purposes. This entry explains the theoretical distinction among achievement, aptitude, and ability tests; describes the primary uses of these tests; and provides a brief overview of the types of subscales widely used in these tests and the constructs they measure.

### Theoretical Distinction

Achievement tests are designed to assess the extent to which a person has developed a specific motor skill or

learned a specific body of knowledge. Typically, an achievement test is administered following a period of instruction designed to teach the motor or cognitive skill to be examined. The prototypical achievement test is the periodic classroom exam that is administered to determine how much the student has learned. Other examples include the written and driving tests taken to secure a driver's license, the Scholastic Assessment Test (SAT) and American College Test (ACT) taken by high school students contemplating college, and the Graduate Records Examination (GRE) taken by college students who want to go to graduate school.

Theoretically, the purpose of the achievement test is descriptive—to measure the extent to which an examinee has mastered a motor skill or area of knowledge. In practice, however, achievement test results often are interpreted as an indicator of future performance. For example, while achievement tests such as the SAT and GRE evaluate the knowledge examinees have accrued as a result of their educational experiences, scores on those tests are used to predict the likelihood of success in more advanced and challenging programs of study. This common practice confounds the performance assessment (i.e., descriptive) function of achievement tests with the prediction goals of aptitude tests.

Many achievement and aptitude tests are very similar in appearance, but the primary purpose of aptitude tests is prediction. They are designed to obtain information that can be used in predicting some aspect of the person's future behavior. Aptitude tests assess the examinee's ability to learn both cognitive and motor skills. Often, scores on a broadly based test of verbal comprehension are used to predict the examinee's potential to learn (and use) new cognitive skills. In fact, the most common use of aptitude tests is to predict future performance in an educational program or occupational setting. However, some aptitude tests measure motor skills (e.g., eye-hand coordination or the time it takes to run a 40-yard dash). Scores on aptitude tests such as these are used to predict the examinee's ability to learn (and use) desirable motor skills.

The distinction between aptitude and ability tests is subtle, and many psychologists and test publishers use the terms interchangeably. In general, however, ability tests assess cognitive and motor skill sets that have been acquired over a long period of time and that are not attributable to any specific program of instruction. For example, intelligence tests such as the Wechsler

Adult Intelligence Scale—Third Edition (WAIS—III) and the Stanford-Binet Intelligence Scales, Fifth Edition (SB5) measure verbal comprehension, working memory, perceptual organization, and processing speed. These abilities are not the result of any specific program of instruction. Instead, they are believed to be a function of the person's native ability to learn from life experiences. Ability tests are descriptive in that they assess people's knowledge and skills, but they are also predictive because they measure qualities that are presumed to influence the person's ability to learn new skills and to solve novel problems.

In summary, psychologists distinguish among achievement, aptitude, and ability tests at a theoretical level. Achievement tests describe people's present status, aptitude tests predict their future behavior, and ability tests assess their innate potential. In practice, however, achievement, aptitude, and ability tests are often similar in form and used for similar purposes.

### Common Variations Among Tests

Psychologists have created such a variety of tests that even developing a system to classify them is challenging. Most tests measure cognitive aptitudes (e.g., the Kendrick Cognitive Tests for the Elderly and the Peabody Individual Achievement Test), but many tests also measure motor skills (e.g., the O'Connor Finger Dexterity Test and the USES General Aptitude Test Battery [GATB]). Most tests require the use of verbal and reading abilities (e.g., the Multidimensional Aptitude Battery [MAB] and the Differential Aptitude Test [DAT]), but a few use nonverbal means of measuring aptitudes (e.g., Tests of Non-Verbal Intelligence, Second Edition and the Peabody Picture Vocabulary Test). In addition, tests differ in the number of aptitudes they measure, their standardization, and the manner of administration.

### Number of Aptitudes

Some tests measure a single aptitude (e.g., the Electrical and Electronics Test and the Personnel Assessment Selection System) but many measure multiple aptitudes (e.g., the Armed Services Vocational Aptitude Battery [ASVAB] and the Ball Aptitude Battery [BAB]). Both approaches have advantages.

Multi-aptitude batteries obtain information about a broad array of cognitive and motor skills and allow

comparisons of the examinee's relative strengths and weaknesses. These instruments are useful when individuals or organizations are seeking information to guide vocational and educational decisions. Although numerous multi-aptitude and multi-ability test batteries exist, all generally measure a relatively standard set of constructs.

More specialized instruments that measure a single construct are useful when more focused predictions are desirable. Obtaining information about constructs like creative and artistic potential often requires the use of specialized instruments designed for that specific purpose. Furthermore, a single aptitude instrument designed to measure reading, math, spatial, or mechanical skills may measure those skills more precisely than a multi-aptitude battery.

### Standardization

Standardized tests are those that have been administered to a group of people (referred to as the norm group) to obtain information about the likelihood of each possible score on the test. Comparing the score of an examinee to the scores obtained by the people composing the norm group allows psychologists to interpret the score. Scores on standardized tests typically are reported in terms of a standard score, an age equivalent score, or a grade equivalent score.

It is critically important that the norm group used to interpret an examinee's score provides a meaningful basis for comparison. For example, it would be misleading to interpret a high school student's achievement test score using a norm group composed of middle school students. Although the problem identified in this example is obvious, more subtle problems have only recently begun to be avoided. For example, comparing the scores a female obtained on a test to the scores obtained by a norm group composed exclusively of males yields a questionable interpretation in many instances. However, this practice was standard not too many years ago.

For this reason, many tests have more than one norm group. A test used with elementary school children, for example, might have a norm group composed of first-grade students, a second norm group composed of second-grade students, and so on up to a norm group composed of sixth graders. In addition, separate norm groups for girls and boys might be available for each grade level. Additional examples of the types of norm groups that could be developed for a test include female college graduates, successful

carpenters, African American lawyers, and enlisted males.

Accurate normative interpretation of a test is not possible without a relevant norm group, but the development of norm groups is costly and time-consuming. This creates two problems. First, many tests have only one or a few norm groups. This practice forces users to base their interpretation on the most relevant norm group rather than on a directly relevant norm group. Sometimes a relevant norm group that matches the gender, cultural background, or ethnic heritage of an examinee is not available, so the user is forced to make the best interpretation possible under the circumstances. Second, the expense of obtaining norm groups also means that some published norm groups are not current. Each cohort of examinees is born into a world that differs in important respects from the preceding cohort. The accuracy and usefulness of normative interpretations of test results declines as the norm group becomes more and more dated.

While almost all aptitude and ability tests are standardized, the typical classroom achievement test is nonstandardized. Generally, scores of nonstandardized tests are reported in terms of the percentage of items answered correctly and are interpreted in terms of a predetermined standard (e.g.,  $A > 90\%$ ,  $B = 89\%–80\%$ ;  $> 70\% = \text{Pass}$  and  $< 69\% = \text{Fail}$ ). Tests that are interpreted by comparing the examinee's performance to a predetermined standard rather than to a norm group are called *criterion-referenced*. Two advantages of criterion-referenced tests are that the scores obtained on such tests are inherently meaningful and no artificial constraints are imposed on the number of examinees that can perform at a given level.

### Test Administration

Most achievement, aptitude, and ability tests can be administered to a single person or to a group of individuals. Historically, the option to administer the test to a group was essential for tests such as the SAT, ACT, and GRE that are taken by hundreds of thousands of people each year. However, in some instances the information that can be obtained from behavioral observations made by a psychologist while administering the test to an individual is quite important. Although more costly and time-consuming, the option of an individualized administration of the test is important. This option is more likely to be desirable when administering a test to children, adolescents,

and individuals with learning disabilities or other problems that might interfere with their performance on the test. Some tests, particularly intelligence tests designed to measure cognitive abilities, are designed exclusively for individual administration.

In the last decade, an additional option for test administration has emerged: computer administration of the test. Computer administration combines the advantage of economic administration to large numbers of individuals with the possibility of some behavioral observations during the administration of the test. For example, response latencies (i.e., the amount of time it takes the examinee to answer the question) can be recorded during computer administration of the test. Furthermore, tests based on item response theory can tailor the test to the ability level of the examinee.

Computer administration is now the primary option for some tests. For example, the GRE is administered by computer to examinees in the United States, Canada, and many other areas of the world unless special arrangements are made for a paper-based administration. This trend will likely accelerate, and it is likely that most widely used standardized tests will provide an option for computer administration within a decade.

## Skills Measured

Hundreds of scales have been developed to measure various facets of achievement, aptitude, and ability. Numerous tests focus on specific content areas such as spatial, mathematical, verbal, and motor skills. Many tests that measure a single cognitive or motor skill provide an alternate (and in some instances a more precise) measure of the skills measured by the multi-aptitude batteries and intelligence tests. Despite this amazing variety of options, most of the leading tests assess the same select set of skills. Although the specific name of the skill varies from test to test and subtle differences exist among similarly named tests, the constructs measured by the various tests are quite similar.

The following sections describe some of the most frequently measured cognitive and motor skills and some of the composite scores obtained by combining information about these skills.

### Cognitive Skills

*Verbal Aptitude:* The ability to understand the meanings of words, sentences, and paragraphs and to use them

effectively. Measures of this skill assess how well an examinee understands ideas expressed in words and how clearly he or she can reason with words. Some tests include separate subscales to measure components of verbal knowledge. For example, the ASVAB includes tests of word knowledge and paragraph comprehension. The WAIS-III, MAB, and SB5 contain vocabulary tests. The SB5 also includes the test Verbal Relations. The DAT contains the following tests: Verbal Reasoning and Language Usage: Spelling and Grammar.

*Numerical Aptitude:* The ability to understand ideas expressed in numbers. Tests include some combination of items that assess numerical computation (i.e., the ability to add, subtract, and perform other arithmetic calculations) and numerical reasoning (i.e., how well an examinee can think and reason with numbers). Scales that assess aspects of this skill are variously titled Arithmetic, Equation Building, Numerical Ability, and Quantitative, among others.

*Spatial Aptitude:* The ability to visualize or form mental images of solids from looking at plans on a flat piece of paper. Some items require people to look at a diagram and determine how an object would look in three-dimensional space if it were completed. Others ask respondents to look at a picture or drawing of a completed object and visualize in three-dimensional space how that object would look if it were rotated into a different position. Related skills are measured in tests titled Block Design, Matrix Reasoning, Matrices, Paper Folding and Cutting, Pattern Analysis, Space Relations, and Spatial.

*Abstract Reasoning:* The ability to understand ideas that are presented without using words or numbers. Tests of abstract reasoning present problems in terms of size, shape, position, or quantity using pictures, shapes, patterns, or some other nonverbal, non-numerical form. Scales measuring spatial aptitude measure one aspect of this ability. Other scales measuring aspects of this ability are titled Form Perception, Object Assembly, Picture Completion, and Picture Arrangement, among others.

*Comprehension:* The ability to use deductive reasoning (and, to a lesser extent, inductive reasoning) to derive solutions for socially relevant problems and issues. These tests assess examinees' practical judgment and common sense and their ability to deal

with their social and cultural environment. Other scales measuring aspects of this aptitude are titled Absurdities and Similarities.

### **Motor Skills**

In a sense motor skills represent the output function of human ability. Understanding and problem solving occur unobserved inside the human brain, but the product of that mental activity is expressed either in words or through some physical activity. Many motor skills tests require people to use their cognitive skills prior to making some physical response. For example, tests of clerical speed and accuracy (i.e., scanning lists of names or street addresses to see if they match or are in alphabetical order) require people to use both cognitive and motor skills. Other examples include block design (i.e., arranging blocks to make a designated design) and digit symbol (i.e., translating randomly arranged symbols into numbers using a key that matches the symbols and numbers).

The following three tests provide purer assessments of motor skills. The tasks they require people to perform are simple and do not require cognitive skill to understand. As such, they provide a clear measure of the individual's ability to perform the physical task.

*Motor Coordination:* The ability to coordinate the eyes and the hands or fingers in quick, precise, accurate movements. Tests of motor coordination present people with a page of small boxes and require them to make a mark in as many boxes as possible within a brief designated time.

*Finger Dexterity:* The ability to make small, rapid, and accurate movements with the fingers such as in typing and to move small objects quickly and accurately such as in assembling two or more objects. Tests of finger dexterity require people to assemble simple objects such as putting a washer on a rivet and to disassemble objects such as taking washers off of rivets and returning the washers and rivets to their storage location.

*Manual Dexterity:* The ability to make coordinated movements with the hands quickly and skillfully. Tests of manual dexterity require people to place objects in designated positions or to turn objects from one position to a designated position.

### **Composite Scores**

Composite scores are scores obtained by combining the scores obtained on two or more tests. Often, test scores are interpreted both in terms of their meaning as a stand-alone score and as part of a composite. The concept of intelligence is probably the best-known composite. Many intelligence tests yield three composite scores: a verbal intelligence, a performance intelligence, and an overall or full-scale intelligence score. Another way to conceptualize intelligence is in terms of the mental processes that form the basis of cognitive behavior. This perspective suggests that intellectual behavior involves understanding, organizing, thinking, and remembering. Important composite scores obtained from tests of cognitive ability that reflect this view of intelligence are verbal comprehension, perceptual organization, processing speed, and working memory.

*Verbal Intelligence:* Obtained by combining scores on measures of verbal, numerical, and spatial aptitude. This composite provides an overall measure of people's abstract reasoning ability and ability to comprehend and learn new skills. This composite is heavily influenced by verbal skills.

*Performance Intelligence:* Obtained by combining scores on measures that require both abstract reasoning and the manipulation of objects such as blocks, beads, pictures, or puzzle pieces. This composite provides a measure of abstract reasoning ability that relies less heavily on the use of words and verbal skills. The ability to understand nonverbal material figures more prominently in this composite.

*Intelligence:* Obtained by combining scores on verbal intelligence and performance intelligence. In tests such as the WAIS-III, MAB, and SB5, this composite incorporates information from verbal and performance composites of five or six tests each. In multi-aptitude batteries such as the DAT and USES GATB, this composite incorporates information from measures of verbal aptitude, numerical aptitude, and spatial aptitude.

*Verbal Comprehension:* This composite provides an overall measure of the individual's ability to understand and work with verbal information. It is obtained by combining scores on measures that assess

vocabulary, general information, and the ability to work with ambiguous information to solve problems when presented in verbal form.

**Perceptual Organization:** This composite provides information about the individual's ability to analyze information that is presented in a nonverbal form and to organize it into a meaningful pattern. It is obtained by combining scores on measures that require the individual to work with pictures, blocks, or matrices.

**Processing Speed:** This composite provides information about the speed with which the person can work with abstract symbols. It is obtained by combining scores on tests that assess the ability to work with abstract symbols that do not have any readily accessible verbal meaning.

**Working Memory:** This composite provides information about the person's ability to hold information in memory and work with it to solve problems. It is obtained by combining scores on tests that require the individual to remember patterns formed by pictures of beads, numbers, and letters.

### Enduring Contribution

The development of the psychological test is one of the most important and enduring contributions of psychology to civilization. Indeed, noted psychologists René V. Dawis and David Lubinski regard psychological tests as serving the same function for psychologists that the microscope and telescope serve for microbiologists and astronomers. Tests provide psychologists with the ability to see phenomena that would otherwise be invisible. Many of the enriching benefits psychology has contributed to modern day society would not have been possible without the use of psychological tests.

Early psychologists began work on the first tests of achievement, aptitude, and ability in the late 1800s. Research and innovation up to World War II focused largely on the development of methods for measuring vocational interests and cognitive and motor skills. The modern science of psychological measurement is attributable to decades of research on tests, as is the fruitful diversity of tests developed by psychologists. Although psychologists have conscientiously developed tests to address the full range of social needs,

their productivity in the area of achievement, aptitude, and ability testing is unsurpassed.

---

## ACTION THEORY

---

Action theory is based on a school of thought in philosophy, social and cognitive psychology, neurology, and organizational behavior as well as in counseling and career development. This school of thought addresses the intentional, goal-directed nature of

human behavior. It has historical roots in the works of George Herbert Mead, Talcott Parsons, and Lev Vygotsky, among others. Action theory has been referred to as a language for how people engage themselves in their daily lives by focusing specifically on processes across time. It takes a teleological perspective of human behavior, thus seeking explanations primarily in the goals of behavior rather than in their causes. Furthermore, action theory is not a theory in the traditional sense, whose purpose is to generate specific hypotheses that can be tested and subsequently accepted or rejected as part of the canon of science. Rather, it is more like a metatheory that provides a guiding framework for understanding human behavior.

Action theory has been applied to counseling and career development and has been found to be heuristic for several reasons. Counseling is essentially a practice that has goal-directed behavior at its center. Career development also involves goals, intentions, plans, and emotional and cognitive processes over time, all of which are addressed in action theory.

In providing a comprehensive framework, action theory recognizes that action can be seen from three perspectives: social meaning; internal processes, that is, the cognitions and emotions that guide and steer action; and the specific behavioral elements that actually comprise the external behavior, including language. For example, one can readily see that writing an e-mail message or having dinner has social meaning. These actions are readily understood by both participants and observers. They are socially meaningful in that society has constructed various norms, rules, and institutions that serve to construct their meaningfulness. People use cognitive and emotional processes to steer their behavior in these actions and rely on language, skills, habits, and resources to actually implement the action. Action theory also reflects the notion that goals are hierarchically ordered across time—that is, some goals are more important than others and may persist for longer periods of time.

### **Application of Action Theory to Counseling and Vocational Psychology**

Action theory has been applied to counseling and vocational psychology by providing new understandings of career development, creating new research capabilities, and developing new and enhancing existing interventions.

### ***An Alternative Epistemology***

The most important epistemological shift that action theory provides is that our understanding of career behavior is not primarily represented by a series of causal statements. Rather it is based on an epistemology that knowledge and meaning are induced and constructed through action, particularly as researchers and practitioners focus on processes and base knowledge generation on language that reflects everyday experience. Specifically, in this epistemology, new knowledge is generated by interpreting for meaning, analyzing for function, and observing for behavior.

### ***Focus on the Social***

Action theory represents part of the substantial shift in counseling and career development, given the emphasis on cultural and contextual perspectives, that focuses on the social rather than on the individual. Specifically, a radical departure from the understanding of vocation as an individual process was operationalized in the contextual action theory of career by directing attention to the joint actions and projects of those centrally involved in each other's lives. For example, in several studies in the past few years, action theory researchers have illustrated how the relationship between parents and adolescents figures centrally in the joint career processes, and indeed career projects are subsumed by relationship and communication goals.

### ***Conceptualizing Action-Project-Career***

One of the contributions of action theory is the conceptualization of the connection among *action*, *project*, and *career*. Here action refers to short-term, goal-directed behavior, and project to a series of actions with a common goal over a midterm time period. When projects coalesce or are constructed as having a common or overarching goal over the long term, they can be considered as career. Projects and careers can be both prospective and retrospective. This conceptualization places action as central to career, and it does not isolate career as strictly an occupational construct. Thus, this conceptualization does not represent the application of psychology to career, but is a psychology in which career has a central place.

## **The Action-Project Method**

In recent research in vocational psychology, action theory researchers have developed a qualitative research method, identified as the action-project method, that has broad applications for use in research in counseling, vocational psychology, and other areas that involve human action. This method has unique units of analysis and data gathering procedures that, when used together in the study of human social processes, can generate findings that speak to the systems of action (i.e., actions, projects, and career), to the ways actions are organized (i.e., as goals, functional steps, and behavioral elements), and to the commonalities and discrepancies between them.

Although researchers have used this method as a qualitative method, it is not exclusively limited to qualitative data. There are aspects of data gathering that are subject to systematic observation and thus are amenable to quantitative analyses. Other aspects of the data are interpretative and depend on subjective reports and interpretation within a meaning community. Data from all perspectives on action, that is, manifest behavior, internal processes, and social meaning, are critical as each contributes to understanding action. This method is enhanced by the use of a video recall procedure, called the *self-confrontation interview*, in which participants have the opportunity to see a videotape of and recall internal process during a recent action.

## **Context**

In action theory, context is represented in and through actions, projects, and career. Actions are embedded in their contexts. They are the person's agentic engagement with the circumstances of his or her own life and more specifically the joint actors' agentic engagement with the circumstances of their lives together.

## **Developing New and Enhancing Established Interventions**

### **Connecting Theory and Practice**

A long-standing issue in vocational psychology is that, while there have been theories of career development, there have not been explicit theories of career counseling. Simply put, theory and practice have

developed separately. Contextual action theory is equally an approach to career counseling practice as it is to knowledge generation about the career process. It allows the counselor and client to address goals in counseling without being too rational, to address cognitive-emotional processing without subscribing simply to an information processing approach, and to address habitual behavior and automatic processes without relying too much on physiological or unconscious processes.

## **Joint Action and Self-Confrontation in Counseling**

Anecdotal evidence suggests that participating in joint action and self-confrontation in counseling can make a difference in the lives of clients. These procedures seem to help clients make joint goals explicit and recognize that they are shared. Clients also appear to appreciate the opportunity to see themselves in action during the video recall and in a sense construct that narrative of that action through recalling their internal processes.

## **Working With Projects**

The concept of joint project adds significantly to practice in the field of vocational psychology. Because project is more time limited, it is more accessible and perhaps more under the control of the client than the construct of career is. In addition, project has the advantage of capturing the agency of the person. It is linked to career, and it is the level that best reflects the joint action between the counselor and the client.

## ADULT CAREER CONCERNS INVENTORY

---

The career concerns presented to counselors by adults vary widely. Some clients are making new career choices, others are coping with adjustment problems, and still others are planning retirement. To identify the career issues that most concern an individual, Donald Super, Albert Thompson, and Richard Lindeman constructed the Adult Career Concerns inventory (ACCI). The ACCI contains 61 items and takes approximately 20 minutes to complete. The first 60 items ask individuals to indicate their degree of concern about coping behaviors that address a sequence of vocational development tasks. The final item inquires about the individual's current career change status.

The ACCI operationally defines Super's model of career adaptability in adulthood. This model postulates that individuals are likely to progress through

four stages as they cycle through an occupational position or job. The length of an occupational cycle can last 30 months (called a minicycle) or 30 years (called a maxicycle) depending on the circumstances of the individual's career pattern. The four major stages in either a mini- or maxicycle are exploration, establishment, maintenance, and disengagement. For each stage, the ACCI measures 15 coping behaviors that deal with progressing through that stage. The 15 coping behaviors in each of the four stages are further divided into subscales consisting of five items each that measure three specific tasks for each stage.

The three tasks of the exploration stage are crystallization, specification, and implementation. These tasks of exploration require that an individual crystallize his or her vocational self-concept and translate it into a general preference for a group of similar occupations, then reduce that group to specify a single specific occupational choice, and eventually to implement the specified choice by gaining employment in that occupation. The three tasks of the establishment stage are stabilizing, consolidating, and advancing, where one is required to adapt to the culture of the organization and show competence in one's job-related tasks, develop a conscientious and disciplined work ethic while establishing friendly and collaborative relationships, and show initiative in order to gain promotion. The three tasks of the maintenance stage are not characterized by progress; rather, they deal with preservation. As such, the tasks deal with the manner in which an individual seeks to maintain his or her current position. The three styles of maintenance are upholding, updating, and innovating, and involve maintaining one's work-related responsibilities, updating one's knowledge and skills, and seeking new ways to complete tasks more efficiently. Finally, the disengagement stage involves the tasks by which an individual leaves one job or occupation in order to transition to another job or eventually into retirement living. Disengagement involves deceleration as one manages her or his time between fulfilling current work responsibilities and exploring new possibilities.

The ACCI is copyrighted to Vocopher and is available free in electronic format via the Internet at [www.vocopher.com](http://www.vocopher.com).

## ADULTS IN TRANSITION

---

Adults experience a wide variety of transitions including shifting from school to work, marriage, divorce, birth of a child, death of a loved one, adjustments to serious injuries, relocations, and, particularly, career transitions. Since the latter part of the 20th century, a rapidly changing global economy and technological advances have demanded that people adjust to the changing context affecting their work lives. Coping with these challenges requires increased awareness of one's self, of the world of work, and of adaptive strategies for making wise career decisions. The following sections emphasize various career-related transition types, theories, stages, special populations, and implications for career counseling.

### Types of Transition

Transitions may be categorized as anticipated, unanticipated, or even nonevents. Moreover, these events can occur abruptly, such as in the case of accidents, or more gradually, such as adjustment to planned promotions or career transitions. A transition may be defined as an event or nonevent resulting in a change of assumptions about self and the environment and thus requires corresponding change in one's behavior and relationships. For career counselors, it is important to understand the nature and context of the transition.

### Anticipated Career Transitions

Some transitions occur at expected times and can be approached strategically. The initial planned career transition that most adults face is switching from school to work, with other transitions including searching out and changing careers and retirement. Unlike in other career transitions, the individual asserts great control in initiating change. This process typically involves gains, losses, and significant role shifts across the life span. Being able to think about and rehearse these changes in roles can increase one's level of preparation, thus allowing for successful transitions.

### Unanticipated Career Transitions

Unanticipated career transitions often involve a sense of crisis and are not usually associated with planned life cycle transitions. These unanticipated events can happen as a result of being fired or demoted, of sudden illness, of a premature death of a spouse, or of a natural disaster. Sudden plant closures or reductions in force (RIF) exemplify unanticipated career transitions. Although a plant closure may be announced and support for the transition provided, a RIF may result in a notice shortly prior to termination.

### Nonevents

Nonevents are those events that a person has planned for and expected, but do not materialize, such as a marriage that did not occur, a promotion that failed to happen, or an unrealized dream. Another example of a nonevent is if a person planned to retire at age 62, but was not able to do so due to financial limitations. Nonevents can be categorized as personal, ripple, resultant, or delayed. Personal nonevents are individualized nonevents, such as a job change that never happened. A ripple nonevent results as a consequence of another person's nonevent such as a spouse losing a job, hindering a planned retirement. The resultant nonevent occurs when either an anticipated or unanticipated event develops, causing a nonevent such as failing to graduate, effectively blocking a planned career. Delayed events represent a situation where a nonevent occurs, but the person continues to hope that the event is only delayed and will eventually happen, such as a delayed promotion. Theories have been developed over the last century to help individuals cope with these types of transitions.

## Theoretical Background

Career theories have been continually updated since Frank Parsons's early work on vocational choice. These changes were driven by industrialization, urbanization, immigration, and globalization. Parsons is credited as the father of vocational psychology. Prior to Parsons's time, occupational choice and satisfaction related more to a person's social class than to his or her choice. Industrialization allowed more individuals the opportunity and volition to engage in personally satisfying careers that provided a sense of security, dignity, and that matched their interests and values. Over a century since Parsons's time, parallel issues affect today's workers, though globalization presently is the main driving force instead of industrialization. Whereas the vocational issues that Parsons addressed involved a changing emphasis from agricultural to industrial opportunities within the United States, rapidly developing technologies and the increasing pressures of a global economy are presently paramount. Today, occupations are not simply shifting from one industry or area within the country, but the work is being sent to areas around the world. While new opportunities have opened up for workers, most continually struggle to cope and adapt to situations over which they have little or no control.

Career transition concerns and coping strategies are likely to vary across a life span. Theories such as Donald Super's life-span, life-space vocational developmental theory are intended to cover a person's career and life roles across the life span. His integrative theory was established during an era in which a person predictably and uniformly left school, obtained employment, and eventually retired. Although Super recognized the necessity of being ready to cope with work environments and occupations that are likely to change, his term *career maturity* implied a typical or natural progression from school, to work, to retirement.

To address the changing nature of careers, theorists have updated the concept of career maturity, considering it more appropriately as career adaptability, which has been placed at the core of career construction theory. Career adaptability is a psychosocial construct that denotes an individual's readiness and resources for coping with current and imminent vocational development tasks, occupational transitions, and personal traumas. Insights from this concept provide a framework for dealing with unplanned changes. Individuals who are able to adapt and navigate through educational and

career transitions do so along dimensions of concern about one's future work life, control over one's career future, curiosity to explore future selves and scenarios, and the confidence to seek one's career goals.

## Transition Stages

Career transitions inherently involve a process that occurs over time. Therefore, any consideration of transitions must address the complex interactions between the individual, significant others, and the cultural context of the transition. Theorists have proposed that individuals experience four stages in career transitions—moving in, moving through, moving out, and moving in again. Research indicates that people experience a variety of issues related to each stage. During the moving in stage, many employers will fail to provide sufficient job orientation. As a result, 50%–60% of newly hired individuals leave their job in the first 7 months. This stage of starting a new job requires knowing the expectations of peers, subordinates, supervisors, and job tasks. Moreover, workers must recognize that openness to this new information can help them embrace the new system and environment. In order to accomplish this, the person needs to understand the expectations regarding his or her new position and the culture of the environment, understanding the explicit and implicit norms and being aware that he or she is likely to feel marginalized initially.

As the person adjusts, he or she enters into the moving through stage. At this point some people may feel that their careers have reached a plateau. A person may also fear being stuck in a dead-end job, feel loneliness or that he or she is lacking in competence, or be concerned about managing competing demands. Strategies for addressing demands of this stage can be organized into three approaches. *Forming* is a way for individuals to gather information through exploration, innovation, and invention. *Norming* allows the individual to extend and improve upon what has been done in the past. Finally, *fulfilling* is a type of transformation involving integration of old and new ideas.

The third stage is the moving out stage. This is a common experience for a variety of reasons, such as a reduction in force, retirement, planned career change, or a layoff. It is both a time of distress as well as an opportunity for a new beginning, depending on how one approaches the change. Working through this stage is similar to working through the grief process, which is characterized by denial and isolation, anger

and resentment, bargaining, preparatory depression, and finally acceptance. Individuals must recognize the importance of moving through stages and not getting stuck. Some may not even be aware of the stages or the nature of what happens in the stages.

The fourth stage, moving in again, involves the individual's attempts to find and adapt to a new occupation or setting. It is helpful for support systems, such as family, friends, and even former coworkers, to find ways to cope with the unemployment during this stage. Coping strategies can involve joining support groups, keeping busy with other productive activities, and taking an active approach to career and educational exploration. During this stage, it is likely that individuals and their families will experience moments of despair or frustration. Instead of moving into a new job, many individuals transition into an educational setting. Although starting a new job, changing careers, going back to school, or retiring involve unique concerns and outcomes, the transitional issues remain the same: Individuals need to understand the culture of the educational setting, expectations for performance, technology and skills involved in returning to school, and seek strategies for feeling connected to the community again.

### Implications for Counseling

To assist individuals with transitions, it is important to conduct an adequate assessment of their values, interests, skills, and personality and to note the importance of coping, social support, and so on. For coping resources, it may be useful to understand the four S's of Situation, Self, Support, and Strategies, which address the current situation, the person's unique patterning of traits and identity, the available resources, the social support, and the coping styles employed. Both emotion-focused and solution-focused approaches can be beneficial in helping the individuals and families process their emotions as well as retain a positive focus on identifying solutions in moving in a new direction. For example, the initial stages of transition may include anger at the company, the situation, or even government policies. Counselors can help dislocated workers understand and appropriately express these emotions. A solution-focused strategy may include a shift from dwelling on what went wrong in the past situation to proactively identifying steps, such as returning to school, to plan for the future.

Counselors can incorporate strategies from career construction theory or the career pathing model to

benefit people in transition. Career construction uses narrative and constructivist approaches to help the person understand his or her career decision influences and choices across the life span. Career construction gives counselors a way to view clients in a broader and integrated fashion that emphasizes human agency through the context of their work and other life themes.

Career pathing starts with a clarification of goals and then utilizes assessments to help the client understand how his or her skills, experience, and personal style align with the skill requirements, performance expectations, and available occupational opportunities. The information gathered can be used to identify the actions and environments, such as training, coaching, additional education, or mentoring, that will be needed to prepare the person for a new occupation.

People naturally seek meaning and order in today's complex world, especially those who have experienced a great deal of change. Because people who have gone through forced or unplanned career changes may experience a sense of loss and reformation of goals, it may be helpful for them to search for a sense of meaning and purpose in the transition. For some, this involves seeking spiritual support and guidance, which can also be another means of engaging social support.

### Special Populations

Because career transitions affect the lives of individuals in such a holistic and sometimes dramatic fashion, it is important to consider how the transition process affects one's personal and emotional well-being. Although certain aspects of transitions are universal (e.g., confusion, adjustment), the unique nature of different transition types can interact with personal and cultural factors to create additional challenges or to buffer the transitional experience. Career transitions might be experienced differently by people depending on gender, age, socioeconomic status, education, race/ethnicity, region of the country, sexual orientation, disability status, and so on. Following are a few examples of special populations.

With regard to women's career development, women may experience barriers in career transition related to work-family stressors, discrimination, or lack of support. For workers transitioning into retirement, the concepts of selection, optimization, and compensation may be particularly relevant. Selection

can involve identifying new goals and choosing plans for retirement. People may shift their allocation of funds to optimize their financial resources and even compensate by choosing activities that are commensurate with changes in health. Similarly, health-related changes in older adults are resulting in families that are sandwiched between trying to take care of their own children while taking on the role of caregiver for aging parents, resulting in additional life stressors. Immigrants may have other stressors based upon their level of acculturation, language skills, discrimination, and cultural differences in their views of occupations and dedication to family.

With the rapid changes involved in globalization, workers need to have an increasing level of adaptability to keep up with the dynamics in the world of work. This involves understanding the occupational requirements as well as having an awareness of their own goals, resources, interests, abilities, and coping style. The associated global changes demand a more educated and nimble workforce. Similarly, career counselors need to keep up with these changes and have the appropriate tools to adequately assist individuals transitioning into a better future. Effective transition interventions can result in improved post-transition adjustment, which allows individuals to navigate future transitions with greater ease and confidence.

## ARMED SERVICES VOCATIONAL APTITUDE BATTERY

---

The ASVAB, shorthand for the Armed Services Vocational Aptitude Battery, anchors the Career Exploration Program (CEP) offered free to schools by the Military Enlistment Processing Command through teams of Educational Services Specialists. The CEP encourages exploration through OCCU-Find, which integrates vocational interests with ASVAB scores and Occupational Information Network. This entry is based on available documentation for the ASVAB and CEP, including journal articles and technical reports. Many issues identified by reviewers of the ASVAB have been addressed, some remain.

### Test Purposes and Scoring

Test purposes served by the ASVAB include career counseling, enlistment screening, and placement. Scores are provided for eight tests, as well as numerous composites including verbal, math, and science–technical; the tests are administered by trained individuals in high schools that make voluntary requests. The ASVAB is rooted in a rich tradition. The Army Alpha test, developed to screen recruits during World War I, evolved into the Army General Classification Test administered to recruits in World

War II. Differentiation of testing occurred across the services until conformance to the ASVAB and the Armed Forces Qualifying Test composite became mandatory. Testing for secondary students began in 1968 as a value-added purpose. Computer-adaptive testing is available, but only for enlistment testing.

Currently, eight tests make up the ASVAB. The raw scores are formed into composites for multiple purposes. The tests, number of items, and content are as follow: General Science (25 items; knowledge of life science, earth and space science, and physical science), Arithmetic Reasoning (30 items; ability to solve basic arithmetic word problems), Word Knowledge (35 items; ability to understand word meaning through synonyms), Paragraph Comprehension (15 items; ability to obtain information from written material), Mathematics Knowledge (25 items; knowledge of mathematical concepts and applications), Electronics Information (20 items; knowledge of electrical current, circuits/devices, and electronic systems), Auto and Shop Information (25 items; knowledge of auto maintenance and repair, wood-metal shop), Mechanical Comprehension (25 items; knowledge of mechanical devices, structural support, and properties of materials). The composition of the ASVAB should be continually scrutinized across purposes and populations.

The focus here is the paper-and-pencil ASVAB used for counseling within the CEP versus the distinct purposes of military testing. A recent refocusing, guided by an expert panel, resulted in enhanced ASVAB scoring moving from a single to a three-construct model and support materials delivered via the Internet. Score reports are well laid out, but may require support to be discussed in family settings after postinterpretation sessions. During the refocusing, a measure of work values was dropped and a measure based on Holland's theory (Interest Finder) was replaced by a scale called Find Your Interests (FYI) delivered by paper or by Web. The FYI is described in the 2005 Counselor's Manual. OCCU-Find, with passcode access generated by a third party, provides test takers, who input their scores, with links to civilian and military jobs aligned with the Occupational Information Network. An update of OCCU-Find to create alignments to more occupations is under way.

The ASVAB is an intersection among societal institutions, namely testing and occupational information; the armed services; and education. Testing as an institution creates consequences for individuals.

Harley E. Baker noted in 2002 that the goal of the CEP program is to present appropriate norm information for secondary and postsecondary career counseling. Norms by grade and gender are derived from the regularly updated Profile of American Youth surveys. Two important aspects of the ASVAB and CEP are the validity of score interpretations for multiple purposes and receptiveness in the test-user and test-taker populations. Baker's research showed reductions in career indecision for a group of Student Testing Program participants compared to two control groups. Score interpretations would be enhanced by investigating distal career outcomes for civilian and military jobs. As a voluntary tool, patterns of requests over time should be informative to developers and users. And despite concerns, according to CEP staff less than 5% of test takers use their scores for enlistment. Schools are given substantial latitude in dictating post-ASVAB contact, although No Child Left Behind regulations grant access unrelated to the ASVAB, which might explain misperceptions.

## Evaluation of the ASVAB

Resources, diminishing though they may be, are invested in the CEP and thus meeting objectives, trade offs, and return on investment become legitimate evaluation questions. The ASVAB-CEP is valuable for school districts and especially for those who cannot afford to purchase off-the-shelf tests of abilities and interests and for the development of occupational linkages. The technical characteristics as described in the *Counselor's Manual* seem solid on reliability and validity with known gender differences. Further, due to a misnorming of the ASVAB (admittedly, long ago) that led to acceptance of lower-scoring recruits, substantial attention is paid to quality assurance. A recent technical review by a committee of experts presented 22 recommendations for the ASVAB. The final paragraphs of this review indicated the quality of the research base with acknowledgment of slow acceptance of innovations by the Department of Defense. The ultimate effect of this review on the CEP is unknown because of its focus on the military testing program. The ASVAB can still be improved for all its purposes.

## ASSESSMENT

---

The assessment of different measures, such as an individual's interests or personality, can influence career development and counseling, giving both the individual and the career counselor useful information for decision making. This entry discusses three central points regarding career assessment: (1) career assessment has a long and distinguished history forged by some of the leading test developers in psychology; (2) the reliability, validity, and usefulness of career assessment measures are unsurpassed in psychology; and (3) comprehensive and multivariate assessment with a variety of high-quality and specific measures will best reflect the individuality that underlies career development.

### Standing on the Shoulders of Giants

Modern psychological assessment began just over 100 years ago when Alfred Binet created the first

intelligence test in 1905. Some 15 years later at Carnegie Institute of Technology, a number of pioneering psychologists were devising ways to measure vocational interests. From that work emerged in 1927 E. K. Strong's Vocational Interest Blank, a powerful and practical measure that has been revised and expanded over its 80-year history by leading psychologists. Today, the Strong Interest Inventory (Strong) is an icon of career assessment, and it illustrates many of the important ways that individuality can be measured to give meaning to career decisions.

People's responses to career inventories matter. Career assessment, as well as work life, has undergone sea changes since those early beginnings. The world of work is very different now than it was 80 years ago when the Strong began. Strong's first samples were often Stanford undergraduates, and they were exclusively male. His early work with working adults was exclusively with men; and in fact, he did not believe that women's interests were well focused. Today, women are the majority in many professional schools such as veterinary medicine, human medicine, and law. Women's scores on scales for leadership and academic achievement equal or exceed those of men. The validity, meaning, and implications of career measures for women are every bit as good as they are for men. Moreover, many career assessment tools appear to have good cross-cultural validity, both globally and across U.S. ethnic and minority groups.

Also, in the past 30–40 years, the kinds of constructs that can be usefully measured in career inventories have greatly expanded beyond interests. What interests (or disgusts) a person is still centrally important to career life, but there are also many other important things. Assessment across diverse domains is the keystone of vocational psychology. Most revolutionary has been Nancy Betz and Gail Hackett's 1981 adaptation of Albert Bandura's ideas of social agency to the theory and constructs of career self-efficacy. Moreover, personality measures are now recognized for their close links to educational and work life. There are many hints that some early personality dispositions may be causal for the development of other career inclinations, such as interests, self-efficacy, and satisfaction.

### Robust Psychometrics in Career Assessment

The quality of measures in career assessment is as good as any area of psychological assessment. The meaning

of a measure for career counseling derives from its reliability and validity. Meaning rests on scale quality. The pioneers in career assessment 70 years ago, such as Strong, Frederic Kuder, and D. G. Paterson, were astutely attentive to reliability and validity. Developers of career measures since then have stood on the shoulders of these giants. Strong launched the empirical, criterion-based occupational scale and showed with decades-long longitudinal studies that interests of adults are quite stable. Kuder pioneered the concept of internal consistency underlying content scales with high homogeneity. In the late 1960s, David Campbell merged these kinds of scales in the Strong as he brought John Holland's content-based concepts to Strong's empiricism. In the current 2005 revision of the Strong, the internal consistency reliabilities for those Holland scales are all .90 or more.

Career measures are robust because career constructs are robust. People differ tremendously in how they see themselves and their work lives. If test developers ask physicists if they *like* calculus, 90% will say yes, but an equal number of car salespeople will say they *dislike* calculus. In other words, how people feel about mathematics, whether they enjoy it or can do it, comprises potent dimensions of individual differences. Most people develop these math cognitions and emotions in their youth and persist with these reactions to math throughout their lives. They become part of one's persona and sense of personal agency. Test developers can readily construct measures of math interests or self-efficacy with high reliability. These measures in turn have potent validity and meaning for both practice and science. One's reactions to math cascade throughout the career development space. They determine how one chooses to embrace or flee a college major in accounting, physics, engineering, or actuarial science. Such college majors in turn have lifelong effects on the course of careers. Reactions to math tend to have high test-retest reliability and high predictive validity for many of career life outcomes. An accountant, physicist, or actuary who hated or feared math would certainly be an outlier.

How one feels about math is one of the most potent dimensions of individuality in career space. There are many other practically significant dimensions. The number of individual differences variables in the self-report realm that importantly affect career life probably exceeds 50. This assertion, based on the trend of recent research, clearly flies in the face of Holland's triumphal advocacy for six career types. Certainly, those six Holland dimensions are an effective and

efficient summary of one's career persona. (They have reliabilities of .90 on the Strong partly because they are long scales.) So if one is an enterprising type, looking toward business and leadership is the right first step. However, within the enterprising domain are crucial facets such as management, entrepreneurship, sales, marketing and advertising, public speaking, law, and politics. Those facets are moderately correlated for a group of people, but individuals with an enterprising bent often differ tremendously on those specific facets. Those facets add very substantially to the meaning and validity of career assessment of individuals. Courses of study, such as college majors, are closely tied to those facets, so a student is well served to have knowledge about those facets. A marketing and advertising major is quite different from a political science major, as are the people moving into careers from those majors.

### **Toward Comprehensive and Multivariate Assessment**

Quite paradoxically, the simplest assessment systems, such as Holland's six broad scales, have prevailed in the last 4 decades along with complex systems with specific scales. The best example is the Strong, as revised by Campbell. The Strong, since then, has contained six broad Holland scales as well as 23–30 Basic Interest Scales (BISs) arrayed under the Holland scales. In the Strong, simplicity of broad scales coexists with complexity of specific BISs. The Holland scales enable a three-letter code that has proved enormously popular in understanding Holland's theory and simplifying career counseling. At the same time, multivariate research (e.g., Donnay & Borgen, 1996) has shown that specific scales such as the BISs increase validity severalfold over the Holland scales for specific criteria such as college major and adult occupation. Campbell's Interest and Skill Survey is similarly structured so that the same conclusions apply to it. The simple six-dimensional system is practically efficient and easy to apply, even though important additional valid variance resides in the specific facets. The same phenomenon has occurred in personality assessment where the simplest systems have become the most popular and widely applied even though there is more valid and meaningful variance remaining in specific facets. The clear examples here are the Myers-Briggs Type Indicator and measures of the Big Five personality dimensions.

In the past decade there has been a surge of studies showing how personality, interests, and self-efficacy are interwoven and linked to career development. The evidence shows not only that these domains overlap substantially, but also that they contribute incremental validity in explaining important career outcomes. When specific scales are constructed as homogeneous content scales, it is possible to combine them in linear composites that predict complex, heterogeneous criteria, such as membership in a college major or occupation. Thus, for example, the ingredients of marketing and advertising are a combination of artistic creativity, writing, public speaking, management, and marketing. These are likely the ingredients of Strong's traditional occupational scale for marketing and advertising; but because occupational scales are actuarial, constructed with blind empiricism, their content has always been opaque. Now, with a multivariate approach to content scales, counselors can match people to college majors and occupations and also make transparent the ingredients of that process. That enables useful career interventions. For example, a student aspiring to a career in marketing, but with low public speaking scores, can seek life experiences to enhance those scores.

Among the 50 plus dimensions a career counselor might have in a comprehensive tool kit are such diverse assessments as introversion–extraversion, optimism, anxiety, risk taking, academic orientation, teamwork, leadership, creativity, career maturity, career indecision, career decision-making self-efficacy, well-being, construal of possible selves, religiosity, altruism, profit-orientation, mechanical activities, athleticism, teaching, music, artistic creativity, selling, accounting, investing, and information technology. Only the most data-driven counselor will want to integrate so many measures. Test developers must organize this cornucopia in a computer-based system that is user friendly and coherent in highlighting the salient scores for counselor and client. Aided by the Holland classification, many comprehensive inventories, such as the Strong and the Campbell Interest and Skill Survey, go a long way toward doing this. Test developers and other researchers also need to demonstrate the incremental validity of this large number of measures to show that a new measure brings utility not already present in prior measures. This is a large and continuing endeavor.

## Top 10 Tools for the Career Counselor's Toolkit

Here are several kinds of measures that are likely to be useful in career assessment, dependent to some degree on the setting. These are all subjective self-report measures. Some of these inventories have very long histories; others are recently developed or are still being refined and have yet to be widely accepted. Some counselors in some settings may equally need objective measures of cognitive skills, or even behavioral samples.

- Comprehensive interest inventory with broad and specific measures
- Comprehensive personality inventory identifying strengths in normal people
- Comprehensive confidence inventory with broad and specific measures
- Measure of work and life values
- Measure of career indecision
- Life satisfaction or well-being measure
- Job or college satisfaction measure
- Measure of career maturity
- Measure of career decision-making self-efficacy
- Career goal-setting inventory

## CAPA Assessment System

The CAPA Assessment System of Nancy Betz and Fred Borgen exemplifies a comprehensive, computer-based system that incorporates measures of interests, self-efficacy (confidence), and personality strengths. The CAPA Interest Inventory includes 47 broad and specific scales, and the parallel CAPA Confidence Inventory includes 39 broad and specific scales. These inventories also contain Life Engagement Scales, measuring such dimensions as academic achievement, extraversion, leadership, and risk taking. These two inventories have been combined in a computerized, online system that assists college students in exploring majors that best match their interests and confidence. Finally, the Healthy Personality Inventory provides 17 scales measuring strengths such as creative, outgoing, and relaxed.

The Betz and Borgen CAPA Assessment System has college majors scales that are linear composites of specific interests and confidence. These new scales, based on modern multivariate methods, can predict

a complex criterion, as can Strong's venerable occupational scales. They have psychometric properties (namely, heterogeneity and diverse content) that are similar to Strong's occupational scales of 1927, yet they are created in an entirely different way. They are based on specific content dimensions known to be the ingredients of a particular major. Thus, students can be shown quite transparently how their individuality matches the typical characteristics of a major. A similar approach can be devised for occupations and for clusters of similar occupations. All of this can be implemented in an online system that provides sophisticated interpretation and links instantly to other sources of information or exploration.

---

## ATTACHMENT THEORY

---

Attachment theory provides a useful theoretical framework for understanding how relationships function to facilitate or hinder developmental progress, such as progress in career development. A central tenet of this theory concerns the central role of attachments as enduring emotional bonds of substantial intensity that influence healthy development and participation in satisfying relationships. Regularities in interactions with caregivers provide children with a sense of security. As individuals mature, cognitive representations (schemas)—or internal working models of attachment relationships—develop and become essential to the experience of security throughout the life span and are predictive of a number of adaptive outcomes. These models become activated and essential during times of stress. Continued participation in mutually satisfying relationships plays a significant role in healthy human development across the life span. Individuals at any age are better adjusted when they have confidence in the accessibility and responsiveness of a trusted other.

Anxiety generated by new situations, such as those encountered when engaging in career tasks, can be alleviated through the experience of attachment to a significant person in one's life who can provide emotional security. This relationship, referred to as the *secure base*, can provide some of the necessary ingredients for successful adaptation to a wide range of new contexts. The transition to a new work environment, which is undoubtedly even more complex for young people leaving school, represents the sort of challenge for which the experience of a secure base would be particularly important.

Much of the research on family relationships has investigated the role of attachment on various career behaviors. Specifically, attachment has consistently been found to be positively related to college students' degree of vocational exploration, career decision making, educational and career aspirations,

expectations and orientation, and effective and healthy transitions.

Similarly, research has found that high school students who anticipated parental support for certain careers, also valued those careers. There also is support for the role of attachment on other career variables including adult adjustment to work, adaptive relationships at work, and career maturity. In the following sections, more information on career exploration, career decision making, occupational aspirations, expectations, and career orientation, and transitions is provided.

### Career Exploration

Career exploration is an important component in identifying, evaluating, and deciding on vocational alternatives. Career exploration has generally been defined as a process wherein individuals seek out information about themselves and the educational and occupational environment to facilitate progress in career development. It is thought that the experience of felt security within secure attachment relationships facilitates the exploration process, which frequently evokes anxiety.

Research suggests that parental attachment is positively related to vocational exploration. In particular, researchers have found that attachment to both peers and mother (but typically not father) is positively associated with environmental exploration, progress in committing to career choices, and career search self-efficacy. In a sample of high school students, other researchers found that a secure attachment to both parents was positively related to the frequency with which girls engaged in exploratory activities and the diversity of the activities that they engaged in. For boys, no relationship was found between parental attachment and exploratory behaviors. For girls, but not for boys, support has been found for the positive association between attachment to mother and satisfaction with exploration in terms of feeling well informed. The results of these studies suggest that attachment with parents facilitates vocational exploration.

### Career Decision Making

The literature on career decision making includes career decidedness, career commitment, and career decision-making self-efficacy. Progress in moving from an undecided position to a committed position with

respect to career choice is a developmental process that is thought to be influenced by contextual factors such as attachment relationships. It has been suggested that the experience of the secure base fosters the risk taking and experimentation that are integral to the process of deciding on and committing to a career choice. Research suggests that for female college students, attachment to both parents is positively related to commitment to career choices and negatively related to the tendency to foreclose on a career choice (i.e., committing to a career decision without adequately engaging in exploration). For college males, only attachment to father is typically related to commitment and tendency to foreclose. Other research has found that attachment to mother was positively related to committing to a career choice, but to a lesser extent than attachment to peers for both men and women.

Attachment to mother, father, and peers also has been shown to be negatively related to fear of commitment to career choices and positively associated with career decision-making self-efficacy. Other evidence indicates that students who experience greater levels of attachment anxiety (i.e., fear of abandonment coupled with the desire for extreme closeness) also report less vocational self-concept crystallization (i.e., degree of clarity and certainty of self-perception with respect to vocationally relevant attitudes, values, interests, needs, and abilities) and greater global career indecision. The literature on attachment and career decision making suggests that attachment influences the various aspects of the career decision-making process for adolescents, such as career commitment and self-efficacy.

### **Occupational Aspirations, Expectations, and Career Orientation**

Several investigations have provided evidence to suggest that adolescent girls' attachment with their mothers contributes to their career orientation. In a longitudinal study of female high school seniors, researchers have found that attachment to mother during high school contributed to the career aspirations of these women 5 years later, but the effect was mediated through career self-efficacy. Most of the research in this area was conducted on a relatively homogenous sample of predominantly middle- to upper-middle-class European American girls. Research is needed with males and participants who are representative of diverse racial, ethnic, and socioeconomic groups.

## **Transitions**

A number of investigators have argued that an adaptive level of attachment between late adolescents and their parents may be beneficial for developmental progress and adjustment in transitions. Evidence suggests that attachment to parents at the end of high school predicts positive changes in expectations of support and socio-emotional adjustment across the transition to college. Research also has shown that parental attachment is positively related to college student adjustment. One study found that for women, attachment to both parents was related to academic autonomy, and for men, attachment to mother was related only to academic autonomy and academic and personal adjustment. In a related study, college student adjustment was positively related to a secure adult attachment style and was negatively related to fearful and preoccupied attachment styles. Other research demonstrated that the relationship between attachment and college student development was mediated by separation-individuation from parents. Implications of this research suggests a model of individuation-within-relatedness for understanding adolescent development.

## **Summary**

The current literature on attachment relationships and career development is suggestive of a positive relationship between a secure attachment to parents and progress in career development. Although only attachment research was reviewed here, research also implicates the importance of separation-individuation from parents as an important construct that may work in tandem with attachment. In summary, attachment relationships seem to have a particularly significant influence on career progress. It also should be stressed that relational influences on career outcomes should not be examined in isolation from gender, race, ethnicity, and socioeconomic status.

## BIODATA

---

Biodata, or biographical data, are paper and pencil measures that ask respondents to reflect or report on their life experiences. Scores from biodata are typically used in conjunction with other employment measures for predicting individual performance in a given job. Biodata have been used across a wide range of occupations as an indicator of the likelihood of job success, where success may be defined as task-specific job performance, teamwork, or other organizationally relevant outcomes. Biodata can therefore be a useful tool for organizations seeking to examine job applicants' backgrounds in a consistent, transparent, and fair manner. The fundamental premise underlying the use of these measures is that past experience should be a reasonable predictor of future work behavior. That is, it is assumed that individuals shape their life experiences, and they are also shaped by these experiences. Given these processes are relatively continuous over time, having critical information about an individual's previous experiences should allow for making more accurate predictions about future behavior—even above and beyond predictions one could make from measures of cognitive ability, personality, motivation, and interests.

Biodata items can vary substantially in content and specificity. For instance, some items may be relatively personality oriented, making the underlying experiences of interest difficult to identify (e.g., "To what extent does your happiness depend on how things are going at work?"). On the other hand, they may be more situation specific or overt, making it relatively

easier to identify the purpose of the item (e.g., "Approximately how many books have you read in the past three months?"). In all cases, however, biodata items require the respondent to recall and report their characteristics and experiences. Therefore, the usefulness of these items depends in part on the extent to which individuals are able to accurately perceive, store, and recall this information and their willingness to report it truthfully. It is known from the cognitive psychology literature that individuals vary widely in the efficiency and effectiveness of their memory storage and retrieval processes, and it is known from the organizational psychology literature that faking answers to items that have no right answer (such as biodata and personality items) is a serious concern in the employment setting.

In addition to items being covert or overt in nature, the underlying personal characteristics tapped by biodata instruments also vary widely across forms. Either implicitly or by design, biodata items typically reflect specific experiences tied to constructs such as ability, personality, motivation, interpersonal skills, and interests. In some cases, these items may be fairly pure measures of a given construct, but in other cases, the items may relate to several constructs. This clearly has implications for empirically examining and interpreting the underlying factor structure and reliability of biodata instruments. Both test-retest reliability and internal consistency (coefficient alpha) should be considered when examining biodata reliability, with test-retest reliability being more sensible when no strong factors exist in the measure.

Although biodata instruments vary widely in terms of many characteristics (e.g., content, length, scoring),

these measures have consistently been found to demonstrate criterion-related validity across occupations. Correlations between scores on these measures and indices of job performance (e.g., supervisor ratings) tend to be approximately .30. Furthermore, these measures have demonstrated incremental validity above and beyond measures of general cognitive ability and the five-factor model personality constructs (emotional stability, extraversion, openness to experience, agreeableness, conscientiousness). Thus, these assessments provide useful information regarding likely occupational success beyond that provided by measures of broad individual differences, themselves known to be valuable predictors of organizational behavior.

### Item Attributes

As noted, biodata items can differ in a number of ways. F. A. Mael has presented a useful outline of 10 major biodata item attributes.

1. Historical versus hypothetical (i.e., past behaviors versus predicted or anticipated behaviors in “what if” scenarios)
2. External versus internal (i.e., behaviors versus attitudes)
3. Objective versus subjective (i.e., observable-countable events versus self-perceptions)
4. Firsthand versus secondhand (i.e., self-descriptions versus how people would say others describe them)
5. Discrete versus summative (i.e., single events versus averaging over a period of time)
6. Verifiable versus nonverifiable
7. Controllable versus noncontrollable (i.e., circumstances could or could not be influenced by the individual’s own decisions)
8. Equal access versus unequal access (i.e., access to opportunities with respect to the group being tested)
9. Job relevant versus nonjob relevant
10. Noninvasive versus invasive (i.e., matters usually kept private)

### Scoring Biodata Measures

A number of biodata measure scoring methods have been proposed. In situations where linkages between

items and constructs are relatively clear, scoring can be quite straightforward. For example, item content may have been developed to tap a specific set of constructs or categorizations might be supported by subject matter expert item sorting. In these cases, each item might be scored along a single underlying continuum (i.e., more is better), consistent with the approach used with traditional Likert-scale self-report measures of personality.

Alternatively, a criterion-keying approach is typically a more complex scoring method. This approach involves obtaining item responses and relevant criterion scores for a sample of individuals. Mean criterion scores or criterion-related validity coefficients are calculated for each response option, across all items. These values are then used as item response weights for scoring purposes. These are strictly empirical weights that can be adjusted, for example, when there are range restriction effects that can be estimated or when nonlinear patterns are found for what conceptually appear to be relatively continuous response options. Keying items based on empirical relationships can also be carried out using personality or other individual difference measures, rather than a criterion measure. This type of scoring may be particularly useful in situations where respondents are motivated to present themselves in a socially desirable manner (e.g., job applicant contexts). In these situations, it may be relatively easy for test takers to manipulate scores on traditional personality measures, whereas scores on a set of personality-relevant but objective or verifiable biodata items may be less susceptible to this sort of response distortion.

One other approach, referred to as *configural scoring*, involves placing individuals into subgroups based on their profiles of biodata scores. An attempt is made to identify subgroups in an initial sample that are internally consistent but externally distinct. The mean biodata profiles from these subgroups may be linked to relevant organizational criteria and then labeled (e.g., a “goal-oriented leaders” profile). Individuals completing the biodata measure subsequently are assigned to these subgroups based on an index of similarity between their biodata profile and the mean subgroup profile (e.g., squared Euclidean distance or profile correlation). These assignments may operationalize various decisions about individuals such as hiring, placement, training, and development decisions.

Although numerous scoring approaches have proven useful, two general recommendations appear

most appropriate. First, scoring methods should be informed by both rational and empirical considerations. A rational or theory-based approach is often very useful for item development, item revision, and score use and interpretation. Clearly, empirical findings that suggest revisions to the conceptual foundation of the measure should not be ignored; this information may lead to both improved prediction and theoretical understanding. Second, a given approach to item scoring developed on one sample should be cross-validated on an independent sample. Any scoring method with weights derived from one particular sample will capitalize on chance to some degree. Therefore, cross-validation is necessary to ensure that findings from the derivation sample (e.g., strong criterion-related validity, reduced group mean differences) are robust.

### Test-Taker Reactions to Biodata Measures

Given that biodata items ask respondents about personal characteristics and life experiences, the potential for negative test-taker reactions to these instruments exists, particularly when they contain items whose purpose is not transparent. Reviews of test-taker reactions research indicate that, compared with other personnel selection measures, biodata tend to be rated as moderate in terms of favorability. Specifically, these measures generally score around the midpoint of favorability rating scales and are typically rated lower than interviews, resumes, and cognitive ability tests, but higher than integrity tests. However, reactions to biodata measures also vary across studies, likely due to the diversity of these instruments. In general, biodata measures are viewed more favorably when the content is perceived as job relevant and a fair reflection of the individual's life experiences.

## BROWN'S VALUES-BASED CAREER THEORY

Brown's values-based career theory emphasizes the central importance of values in career counseling and occupational choice. *Values* are defined as cognitive structures that are the basis for self-evaluation and one's evaluation of others. Values also have an affective dimension, are the primary basis of goal-directed behavior, and are the stimulus for the development of behavior related to goal attainment. Values have been portrayed as more fundamental traits than interests, and it has been suggested that concerns for values should be the primary consideration in career counseling, without precluding the use of other constructs. The values-based approach is also predicated on the idea that career counseling should in most cases be life-role counseling because of the interaction among life roles and the unlikely outcome that an occupation can satisfy all of an individual's values.

The model assumes three types of values—cultural, work, and life values. Cultural values can be subdivided

into five categories of social relations, time, relationship to nature, activity, and self-control. Work values are those values that clients expect to fulfill as a result of choosing and entering an occupation. Life values are those values that clients expect to have satisfied as a result of the choices they make in their major life roles, such as work, leisure, citizen, and relationships to significant others. Understanding these three types of values provides career counselors with the information needed for lifestyle planning.

Life-career counseling from a values perspective is based on the following assumptions: (1) Highly prioritized work values are the primary basis of career choice. When choosing an occupation to match values is constrained, structuring other life roles in ways that will satisfy highly prioritized life values should be pursued. (2) The most successful decision makers are likely to be those individuals or groups who have a future or past-future time orientation and a doing-activity value. (3) Clients with an individualism social value are required to make a series of estimates about their personal characteristics and the occupations they are considering if they are to be successful. (4) The sources of job satisfaction will vary for people who hold individualism and collateral social values. (5) Job success as determined by the supervisor or employer will be determined by the same factors for people regardless of their social relations value.

Sensitivity and attention must be given to cultural, work, and life values as a counselor works through the following stages of career counseling: client identification, relationship building, goal setting and assessment, problem solving, and termination. Perhaps the most important issue to be addressed during this process is to crystallize and prioritize the client's cultural, work, and life values in the context of life roles. Culturally sensitive interviewing, card sorts, and standardized values clarification surveys are helpful techniques for this process. The Life Values Inventory is an empirically derived values assessment instrument developed from the principles of this model. At the end of the process clients should be aware of their values in the context of life roles; how values influence their motivation, goal setting, self-evaluation and thus satisfaction; and their evaluation of others.

## BUREAU OF LABOR STATISTICS

---

The Bureau of Labor Statistics is an agency with the Department of Labor, whose task it is to gather, analyze, and provide information on all aspects of labor, economics, and the workforce in the United States. The bureau was established by President Chester A. Arthur in 1884 as part of the Department of the Interior.

### Information Available From the Bureau of Labor Statistics

The Bureau of Labor Statistics currently provides data and information in the following areas:

- Inflation and consumer spending
- Wages, earnings, benefits, other compensation
- Productivity, both in the United States and internationally
- Occupational safety and health
- Descriptive information about occupations
- Demographic information about those in and out of the workforce
- Information about industries and the costs of doing business

While the bureau collects its own data, it also utilizes data from the census and various state agencies. The data and reports produced by the bureau are currently available in both print and Web formats. Major publications of interest to career counselors include the *Occupational Outlook Handbook*, the *Occupational Outlook Quarterly*, the *Career Guide to Industries*, and the *Monthly Labor Review*. The *Occupational Outlook Handbook*, first published in 1949, provides information on occupations and preparation for them. The *Occupational Outlook Quarterly*, first published in 1957, was designed to provide more frequent

updates to the *Occupational Outlook Handbook* than were possible with the latter's biennial publication schedule. The *Career Guide to Industries* describes this same information from the perspective of the industry in which the occupation is embedded.

Note that the *Dictionary of Occupational Titles* and subsequent occupational definition system, the *Occupational Information Network* (O\*NET), are publications of the Employment and Training Administration within the Department of Labor, not the Bureau of Labor Statistics.

### History of the Bureau of Labor Statistics

Prior to the establishment of the bureau, the only data available at the national level on employment and labor issues was information gathered as part of the decennial census. The bureau was established in response to a growing awareness of the lack of information for policy making in the area of labor and the conditions of employment. In its early years the bureau produced a number of reports, such as an annual report on industrial depressions (beginning in 1886) and a report on retail prices and wages (1891). Another annual report produced beginning in that same period was titled "The Slums of Baltimore, Chicago, New York, and Philadelphia" (1893) that included not only data on employment, but on such topics as crime, literacy, health, and crowding.

In 1913, the Bureau of Labor Statistics joined three other bureaus (Immigration, Naturalization, and Children's) to form the Department of Labor. Although there have been numerous changes in the bureaus that comprise the Department of Labor over the years, the

Bureau of Labor Statistics has remained a constant component of the Department. Currently, the Bureau of Labor Statistics is joined by the following agencies in the Department of Labor: Employment and Unemployment Statistics, Prices and Living Conditions, Compensation and Working Conditions, and Productivity and Technology. Although the aforementioned agencies are not part of the Bureau of Labor Statistics, their titles provide an idea of the topics on which the bureau, as the research arm of the Department of Labor, conducts research. In addition, the Bureau of Labor Statistics studies and evaluates the research methods used to gather and provide their data.

## **CAMPBELL INTEREST AND SKILL SURVEY**

---

The Campbell Interest and Skill Survey (CISS) is a career assessment instrument that analyzes an individual's self-reported interests and skills to assist in effective career planning and decision making. The CISS provides four kinds of scales that help individuals age 15 through adult understand how their interests and skills relate to important areas in the world of work and to specific occupations, particularly those requiring a college or professional degree. The test's primary author, David P. Campbell, incorporated measures of self-assessed skills into the survey to highlight the importance of an individual's self-confidence in skills when making career decisions. The profile reports both interest and skill scores on 7 Orientation Scales, 29 Basic Scales, 60 Occupational Scales, and 2 Special Scales (Academic Focus and Extraversion), providing comparisons between an individual's strength of interest and strength of self-confidence for each scale. The CISS's innovative combination of interests and skills scales provides the user with valuable information that is unavailable from alternative inventories that measure interests alone. The CISS can be used to identify areas of academic study and to clarify occupations that are likely to lead to both satisfaction and success for traditional-aged and adult students, and to support career changers, transitioning employees in outplacement programs, and preretirees in future career and life planning.

### **History of the Survey's Development**

Campbell developed the CISS building on his more than 30 years of experience in interest measurement research. Campbell's experience with interest measurement research began in 1959 when, as a graduate research assistant at the University of Minnesota, he became involved in revisions of the Strong Vocational Interest Blank (SVIB). After many years on the faculty at Minnesota researching and revising the SVIB, and later the Strong-Campbell Interest Inventory (SCII), Campbell was recruited to the Center for Creative Leadership in 1974 where he continued to develop other assessment instruments. Eventually, in 1988, he ended his professional ties with the developers of the SCII, and turned his focus to developing a new, easy to use survey with both interest and skills scales intended to be free of bias in vocabulary, norms, and profile presentation. Building on his long-term experience on the Board of Directors for National Computer Systems (NCS), Campbell chose NCS—now Pearson Assessments—as the publisher of the CISS in 1992.

### **Item Content**

Campbell carefully selected 320 items for the CISS out of an extensive pool of hundreds of items to avoid content that was biased or offensive and on the basis of item response characteristics. The CISS has 200 interest items. A unique feature of the CISS interest items for occupations is that each occupation is defined. For example, the item for architect reads, "An architect, designing new homes and buildings."

The key strength of the CISS is that it also has 120 skill items that measure individuals' beliefs about their abilities to perform a range of activities. The skill items are designed to be measures of self-confidence in abilities rather than direct measures of skills. Research data reported in the manual indicate that individuals' self-rated skills and behavioral observations of their skills are highly correlated.

The CISS uses a 6-point response format that allows for a refined response to the items and also forces respondents to state at least a mild preference in one direction or the other by eliminating a neutral response. Respondents are asked to rate their level of interest for most of the interest items using the response options: *strongly like*, *like*, *slightly like*, *slightly dislike*, *dislike*, and *strongly dislike*. Respondents are also asked to rate their level of skills for the skill items using: *expert*, *good*, *slightly above average*, *slightly below average*, *poor*, and *none*.

## Scale Construction

### The Orientation Scales

The CISS profile report is organized around seven factors referred to as the Orientation Scales. The Orientation Scales are homogenous scales based upon earlier factor studies of interests by Thurstone, Strong, Holland, and Campbell. After numerous analyses designed to accommodate the Basic Scales, Campbell chose a seven-component structure for the Orientations. Campbell's Orientations are similar to Holland's RIASEC (Realistic, Investigative, Artistic, Social, Enterprising, and Conventional) types, but are described using action-oriented words (gerunds) with clearer meanings more connected to workplace activities. The seven orientations are Influencing, Organizing, Helping, Creating, Analyzing, Producing, and Adventuring.

### Basic Scales

The 29 Basic Scales comprise parallel interest and skill scales that measure individuals' attraction to and confidence in a range of life activities. The Basic Scales are homogeneous subscales of the Orientation Scales and were constructed by identifying items that had high intercorrelations with each other, low correlations with items in other clusters, and appeared to belong together, based on their content.

### Occupational Scales

The 60 Occupational Scales were empirically constructed from a general reference sample made up of all respondents from 65 occupational areas by identifying items that statistically differentiated members of each occupational sample of workers who reported they enjoyed their work. Each Occupational Scale consists of a set of items that varies widely in content, and it is not intuitively obvious which item belongs to which Occupational Scale. The Occupational Interest Scales contain positively and negatively weighted items that reflect both the likes and dislikes of an occupational group. For example, a respondent might score higher on a particular Occupational Scale simply by disliking the same items that members of that Occupational sample disliked. The Occupational Skill Scales, however, contain only positively weighted items—the rationale being that it would be unwise for a client to make a career decision based on negative data, such as, “You have the same lack of skills as an attorney; therefore, you should consider law.” The CISS uses combined gender scales to ease interpretation.

### Special Scales

The Academic Focus Scales, intended to measure respondents' interests and confidence in doing well in formal academic endeavors, were constructed by identifying items that were rated high and low by people with high levels of education and by assigning positive and negative weights, respectively. The Extraversion Scales, which measure respondents' interests and confidence in working with people (as opposed to working alone), were constructed through identifying and positively weighting items that correlated with “Extraverted” and negatively weighting items that correlated with “Introverted” on the Campbell Leadership Index.

## Administration

There are several ways to administer the CISS, including the Internet, local scoring software, an optical scan scoring system, and paper and pencil administrations using a mail-in scoring service to Pearson Assessments. It takes anywhere from 25 to 40 minutes to complete the 320 multiple-choice items.

## Report Format

The CISS results are reported in an appealing profile format with both interest and skill scores presented for each of the Orientation, Basic Interest and Skill, Occupational, and Special Scales. The interest and skill scores are presented both numerically and graphically for ease in interpretability, allowing respondents to compare the strength of their interest with strength of their self-reported skill on each scale. The numerical scores are standard scores based on the reference group, whose distribution is bell shaped with a mean of 50 and a standard deviation of 10. The consistency of score reporting makes it easy to identify scores of 60 and above as high scores, and scores of 40 and below as low across all scales. In addition, the patterns of interest and skill combinations for each scale are further clarified with the following helpful descriptors: Pursue, Develop, Explore, and Avoid, which can enlighten further career exploration and choice.

## Interpretation

The CISS can be taken online by any interested individual without assistance from a career counselor. Respondents are provided helpful online tools to aid in interpretation, such as the CISS Career Planner. However, individuals are encouraged to discuss the CISS profile with a skilled career counselor for help with understanding the profile layout, the definitions of the scales, and the meaning of the scores. An interpretation of the CISS profile from a skilled counselor can be particularly valuable for clients needing help with decision making or with connecting their results to future career exploration.

## CARD SORTS

---

Card sorts are nonstandardized and subjective assessments commonly used in career counseling to help clients clarify their skills and career interests. This entry provides descriptions of the history and varieties of vocational card sorts (VCSs), research findings, and the advantages of using card sorts in career counseling.

## Overview

In this type of assessment, clients typically sort between 30 and 40 cards of various themes or ideas into categories as a way to develop personal or career-related priorities and, as they do so, themes tend to emerge. It is preferable for clients to identify patterns within the sorted categories themselves so that the themes are personally relevant to them. Card sorts are sometimes preferable to more standardized assessments because the information gathered therein is done so informally and through client speech. Therefore, clients are actively engaged in the process of self-awareness. Additionally, through this process counselors can see firsthand how clients organize thoughts and ideas, as the success of the exercise is dependent on the client's ability to engage in the process and recognize and explore patterns or themes.

Any set of ideas may be examined through use of a VCS, including career values, occupations or occupational titles, skills, or college majors. Counselors may also create their own collection of items to reflect a particular theme. The exercise of clients sorting and prioritizing the items within the particular category

appears to be critical to the process. In doing so, the client makes decisions about items relative to one another and expresses his or her reasons for doing so. In working with clients, counselors may offer a more structured setting in which, for example, the client generates a list of occupations to explore. Alternately, the card sort exercise may serve as a springboard for discussion, thus providing ample room for dialogue in a less structured setting. In this way, card sorts can be customized to the needs of a particular client.

### Research

Leona Tyler was the first to describe the VCS in the literature and to provide empirical evidence for their utility. In relation to vocational inventories, such as the Strong Interest Inventory (Strong) or Self-Directed Search (SDS), research on the VCS has received exponentially less attention. This is likely due to many reasons, but most importantly it is because testing a client's interests or skills using inventories preceded the development of card sorts and because inventories as a whole are considered more "research friendly." Card sorts most often need to be completed in the presence of a trained counselor, while inventories can be taken away from the counseling setting, scores can be computed electronically, and inventories such as the Strong and SDS have been validated with thousands of individuals across decades of research.

The research that has been completed on the VCS has mostly related card sort outcomes to vocational inventory outcomes. In a recent review of the literature, studies have shown that clients indicate interest in similar occupations whether a VCS or a vocational inventory is used. Thus, according to this limited body of research, card sorts have appeared to be as valid in determining vocational preferences as inventories.

The degree to which card sorts are helpful with various types of counseling clients has also been researched. For example, a number of studies have separated participants based on levels of career indecision and then had them complete a VCS. Clients who are the most undecided have been consistently found to benefit most from the card sort technique.

Finally, a number of individual studies have been completed with VCSs on various topics. For example, one study found using a VCS with career clients to be a good method of evaluating clients' knowledge of the world of work and the status of their career development. Other studies have found that the card sort method works equally as effectively with students in

both high school and college, and that a VCS may work particularly well with students who have a flat Strong profile.

One of the most widely used and researched card sorts today is the Missouri Occupational Card Sort. Developed for use with undecided college students at a large university, clients learn about themselves through the Holland classification system of personalities and environments. Job tasks and responsibilities are also included on the cards to help clients learn more about each occupation as the cards are sorted.

Although research on VCSs is limited, card sorts have been found to be equally as valid as vocational inventories and to be particularly useful for clients at the beginning stages of their career exploration. These findings may serve to influence the use of card sorts in career counseling practice.

### Advantages in Counseling

Card sorts are one of the techniques career counselors use to help clients clarify their skills, values, and occupational interests. Card sorts are believed to be as effective as standardized assessments in predicting career choice; but because they are subjective in nature and do not produce scores or have norms, their effectiveness depends on the counselor's ability to help the client gain insights and ideas from the results. Card sorts have a number of advantages that make them a valuable tool to use either in place of or in addition to standardized assessments, depending on each client's individual needs. Their advantages are summarized here:

- The short phrases used in card sorts can be more easily read by clients with learning disabilities than checklists often used in paper or computerized assessments.
- The card process can be energizing and engaging because it allows clients to be actively involved in choosing their responses.
- Because of their semistructured nature, card sorts can be modified to meet individual client's needs and used at any point during the counseling process, either as a stand-alone approach or to supplement standardized assessments.
- Card sorts allow for interaction and dialogue between the client and counselor, which can aid in establishing rapport and provide counselors with the opportunity to discuss the rationale for a client's choices. Insights about the client's thought processes can be helpful in

interpreting results of standardized assessments. In addition, viewing the process whereby a client chooses responses, such as the speed or number of changes made in sorting the cards, can be just as revealing as the responses themselves.

- The results are not dependant upon comparison to a norm group, and therefore clients can attach their own individual meaning to card items and apply the results to their needs. Knowing how a client interprets card items can be helpful in understanding his or her worldview and the context in which the client is making decisions. This knowledge can be helpful in working with clients of diverse backgrounds and can give counselors insights about confounding problems interfering with the client's ability to make decisions.
- Card sorts are nonthreatening to individuals who might be wary of standardized tests. In addition, because card items can be moved from one pile to another, clients do not need to be concerned about giving a right or wrong answer, as they might be on a standardized test.

### Additional Advantages

Card sorts may provide clients with the necessary structure to take risks and/or engage in the counseling session. Additionally, collaborating on a task like the card sort may contribute to the formation of the therapeutic relationship and the provision of feedback within the session. Relatedly, counselors may gain insight into clients' cognitive organization by observing how the sorting exercise is conducted and may identify occupational stereotypes or clients' misconceptions about themselves. Moreover, the active nature of the card sort exercise helps to keep the focus on the client and her or his perceptions, thereby minimizing the risk of becoming overly dependent on the counselor. Because card sorts are nonstandardized, they do not rely on statistical data or norm groups. They are flexible and can be adapted to clients from varying backgrounds. Finally, because of the active nature of the process, some researchers have theorized that clients engaged in a card sort may increase their decision-making self-efficacy more than clients who take standardized career assessments.

## CAREER ADVANCEMENT

---

Career advancement has been for decades a topic of many books found in the self-help, career, and especially the business sections of bookstores. It is not a topic commonly found in career counseling or vocational psychology textbooks or journal articles. There are several assumptions and key concepts and characteristics commonly found in books about career advancement. These include the broad assumption that in general people are ambitious and urgently seek to improve their employment situation. These books typically assume that promotions are very important to many people. In other words, these books employ a stereotype worker profile that may be appropriate for some, but is not for all kinds of workers, occupations, job settings, and careers.

The books mix common sense, social science, and self-promotion—all of which presume that the readers are ambitious, active, even aggressive and that they surely want to improve their career by following the

advice found within. The books include information on how to set career goals, overcome workplace fallacies, become a coach or use a coach, find a mentor, evaluate one's job personality, survive the workplace jungle, get ahead if one is employed in the government, and otherwise cover a wide range of ideas that then concludes with rules to follow or steps to take. Books on career advancement often oversimplify the ideas they present. Perhaps this fact is what makes them maintain their readership.

In fact, these assumptions and stereotypes may fit some individuals who are employed in business or management jobs. However, these assumptions do not fit many other workers, occupations, job settings, and careers. For example, these concepts may not fit well, or even at all, with people in social service, trades, health care, technical, or artistic careers.

These how-to-do-it books are aimed at people who want help with perceived problems, and so the books are full of advice. Some of the sources for some of the advice offered in these books are extracted from social, organizational, business, or vocational psychology research or theory, and some are borrowed from career guidance and career assessment fields.

These books typically claim to have answers that will help readers handle ongoing or immediate needs. An example is the book by Richard Bolles, *What Color Is Your Parachute*, which was first published in 1972. It has been a best seller. It presents a philosophy and many ideas derived from psychology, and it even employs a version of John Holland's theory of occupational choice, but it presents it in a derivative format rather than using the terms found in Holland's work. The author's background was neither psychology nor counseling. His first career was the ministry.

The topics covered in these books are wide. They are written for adult readers seeking information about topics such as how to handle a job interview or write a good resume, how to get the next promotion or make career progress over time, or how to handle difficult people at work or even acquire *The Seven Habits of Highly Effective People* as described by Stephen Covey in his 1989 book. Covey's training and employment background is in business. A business background is common with the authors of these publications. Some of the career advancement authors have been employed in human resources positions, or they have been executive recruiters prior to writing a self-help book.

## CAREER ATTITUDES AND STRATEGIES INVENTORY

---

The Career Attitudes and Strategies Inventory (CASI) is a 130-item, paper and pencil, self-report assessment by John L. Holland and Gary D. Gottfredson. The CASI is intended to give the employed or unemployed adult client and career counselor information regarding the client's likelihood of job stability or change, potential career obstacles, or areas for further development. The CASI was developed by two highly respected vocational psychology and career counseling researchers, whose works typically address Holland's RIASEC (Realistic, Investigative, Artistic, Social, Enterprising, and Conventional) theory. The authors of the test note that the CASI should be a supplement to rather than a substitution of interest and ability measures. For example, the manual makes frequent mention of the use of the CASI with some of the other instruments developed to operationalize Holland's theory.

Reviewers have warned that the CASI should be used as a screener or to facilitate discussion between a counselor and a client due to some questionable psychometric data. Yet other reviews do not seem to find a problem with the current psychometric properties of the instrument given its intended use. It seems that most agree that the CASI could use more refinement to address some issues such as norms for special groups and better definition of broad subscales. Overall, the CASI is an interesting, attractive, and easy to use instrument that is useful enough for career counselors to justify continued research and refinement.

CASI items are answered on a 4-point Likert-type scale (*false, mostly false, mostly true, and true*) as they

relate to the test taker. Nine aspects of career or work adaptation are assessed by the CASI: (a) job satisfaction, (b) work involvement, (c) skill development, (d) dominant style, (e) career worries, (f) interpersonal abuse, (g) family commitment, (h) risk-taking style, and (i) geographical barriers.

The manual states that a client can self-score, self-profile, and self-interpret the CASI in about 35 minutes. However, past reviewers of this test supported the use of counselor intervention in the interpretation and discussion of life and career implications relevant to the inventory results. The CASI is published and available for purchase through Psychological Assessment Resources.

The CASI was developed through a commonly utilized three-stage process, which ultimately led to the current version of the measure. The normative group comprises 774 men and women ages 17 to 77 years with education from some high school to postgraduate degrees. The majority of the norm group is European American (79%) with the remaining 21% from other self-identified ethnic groups. Reliability of the test is adequate. The manual reports some validity evidence for the instrument, although this evidence is not well reviewed.

## CAREER BARRIERS INVENTORY

Career barriers have been hypothesized to affect the career development process by inhibiting career aspirations and restricting the range of perceived career opportunities. The Career Barriers Inventory (CBI) is a psychometrically sound, multidimensional, self-report instrument that was developed to assess for career-related barriers. The CBI assesses for a broad array of barriers that college students may perceive. Furthermore, significant gender and racial/ethnic group differences in the perceptions of barriers have been found in the Career Barriers Inventory-Revised (CBI-R).

The original form of the CBI was developed by Jane Swanson and David Tokar to examine a broad realm of barriers that may influence career-related activities. The CBI included 102 items developed to address different types of barriers that may transpire across a range of career-related activities, such as career decision making, college-to-work transition, job performance, work-related discrimination, and work-family balance. The CBI consisted of 18 separate scales. Internal consistency estimates in a sample of college students ranged from 0.53 (*Overqualified for Job Market*) to 0.94 (*Sex Discrimination*). Items for each scale were highly correlated with their respective scales and moderately correlated with one another ( $r = 0.11$  to  $0.68$ ), providing evidence for convergent and discriminant validity.

The original CBI was modified in order to reexamine and redefine the scales, reduce the number of items, clarify item content, and delete overlapping items. The shortened version, the CBI-R, is comprised of 70 items on 13 separate scales that cover a wide range of barriers that college students may perceive. Scales are highly correlated between both versions of the CBI, ranging from 0.72 to 1.00. The 13 scales on the CBI-R include (1) *Sex Discrimination*, (2) *Lack of Confidence*, (3) *Multiple Role Conflict*, (4) *Conflict Between Children and Career Demands*, (5) *Racial Discrimination*, (6) *Inadequate Preparation*, (7) *Disapproval by Significant Others*, (8) *Decision-Making Difficulties*, (9) *Dissatisfaction With Career*, (10) *Discouraged From Choose Nontraditional Careers*, (11) *Disability/Health Concerns*, (12) *Job Market Constraints*, and (13) *Difficulties With Networking/Socialization*. Each scale consists of three to eight items. Internal consistency estimates in samples of college students ranged from 0.64 (*Disapproval by*

*Significant Other, Difficulties With Networking/Socialization*) to 0.86 (*Sex Discrimination*). Inter-correlations among the CBI-R scales vary considerably from 0.27 (*Disapproval by Significant Others* and *Disability/Health Concerns*) to 0.80 (*Racial Discrimination* and *Sex Discrimination*). Gender differences were found on the CBI-R with women scoring higher on *Sex Discrimination*, *Lack of Confidence*, *Multiple-Role Conflict*, *Conflict Between Children and Career Demands*, *Inadequate Preparation*, *Decision-Making Difficulties*, and *Dissatisfaction With Career*. Individuals from racial/ethnic minority backgrounds scored significantly higher on *Racial Discrimination* than their Caucasian counterparts.

## CAREER BELIEFS INVENTORY

---

The Career Beliefs Inventory (CBI) is a tool designed to help people identify career beliefs that may be preventing them from taking action to achieve their career goals. Many people hold beliefs that block their career progress. Maybe they believe that there is only one path to a successful career and that they have already missed one essential step on that path. Maybe they believe they must enter a certain occupation to win family approval. Maybe they believe that hard work is unnecessary until they have clear goals. These are just a few examples of beliefs that have caused troubles for other people and might possibly be interfering with their career progress.

This inventory, consisting of 96 questions, helps individuals examine beliefs about themselves and the

world of work. It identifies 25 belief scales that might possibly be creating difficulties. Career specialists use this inventory as a springboard to discuss attitudes and assumptions that need to be examined when making and implementing career choices. The 25 scales are organized under five categories: current career situation, conditions necessary for happiness, factors influencing decisions, willingness to make changes, and willingness to exert effort. The inventory takes about 25 to 30 minutes to complete.

The CBI was developed from over a thousand stories collected from people who could report a belief that they once held, the trouble it caused, and how they corrected their troublesome beliefs. The reported beliefs were grouped into categories, edited for brevity and clarity, and summarized into 122 items that were then administered to over 7,500 participants. A number of factor analyses were computed from these data, and eventually 25 revised scales were defined based on the 96 best items.

The *CBI Applications and Technical Guide* is the revised manual published in 1999. It contains a summary of the reliability and validity data, directions for use, and a table of norms. The norms would be necessary only if clients wondered how common, or uncommon, their beliefs were. The recommended method for using the CBI, however, is to help people identify beliefs that might be causing trouble for them.

It is used as a conversation starter to begin exploring possible dysfunctional beliefs that may be inhibiting clients from taking appropriate action now.

Two scoring versions are available:

1. Self-Scorable: Users can score their own booklet and see their own results immediately. An explanation of each score is included.
2. Computer Scored: A separate prepaid answer sheet is mailed to CPP, Inc. (formerly Consulting Psychologists Press) for scoring and results are mailed back.

Also available is a client workbook titled *Exploring Your Career Beliefs*. It includes techniques for integrating CBI scores with results from the Strong Interest Inventory and the Myers-Briggs Type Indicator (MBTI).

These materials are distributed by CPP, Inc. They are available online at [www.cpp.com](http://www.cpp.com) or by phone at 1-800-624-1765.

## CAREER CONSTRUCTION THEORY

---

The global economy of the 21st century with its digitalization and worker migration poses new questions about career, especially the question of how individuals can negotiate a lifetime of job changes without losing their sense of self and social identity. Career construction theory responds to the needs of today's mobile workers who may feel fragmented and confused as they encounter the restructuring of occupations and transformation of the labor force. The theory's response asserts that individuals build their careers by imposing meaning on vocational behavior. From a constructionist viewpoint, career denotes a moving perspective that imposes personal meaning on past memories, present experiences, and future aspirations by patterning them into a life theme. It is the meaning contained in these biographical themes that will equip individuals to adapt to the social changes that are playing out in their work lives. This personal meaning replaces the holding environment once provided by organizations that contained the task of self-integration as it cared for, protected, and interpreted experiences to its employees. Today, it is the life story that holds the individual together and provides a biographical bridge with which to cross from one job to the next job.

Using social constructionism as a metatheory, construction theory views careers from a contextual perspective that sees people as self-organizing, self-regulating, and self-defining. Relying on its social constructionist epistemology, the theory reconceptualizes both vocational personality types and vocational tasks. It interprets personality types as processes that

have possibilities, not realities that predict the future. It views developmental tasks as social expectations. Career construction theory then uses the concept of life themes to weave together its conceptualizations of vocational personality and career adaptability into a comprehensive theory of both vocational behavior and career counseling. Stated succinctly, the theory holds that individuals construct their careers by using life themes to integrate the self-organization of personality and the self-extension of career adaptation into a self-defining whole that animates work, directs occupational choice, and shapes vocational adjustment.

### Vocational Personality

Career construction theory defines vocational personality as the constellation of an individual's career-related abilities, needs, values, and interests. The theory discusses personality using the nomenclature and framework of Holland's RIASEC (Realistic, Investigative, Artistic, Social, Enterprising, and Conventional) types because it offers a widely used language for describing the personological results of an individual's efforts at self-organization of his or her skills, interests, and abilities. While adopting Holland's language to articulate accounts of personalities and occupations, career construction theory reminds counselors and researchers that the traits constituting RIASEC types are completely decontextualized and quite abstract. It is easy to forget that the traits, especially when denoted with nouns rather than verbs, are really just strategies for adapting. They are dynamic processes that present possibilities, and they should not be reified into realist tools for predicting the future.

Career-related abilities, interests, and values are relational phenomena that reflect socially constituted meanings and categories that should not be considered as anything more than similarities. Therefore, career construction theory asserts that vocational personality types and occupational interests are simply resemblances to socially constructed clusters of attitudes and skills. They have no reality or truth value outside themselves because they depend on the social constructions of time, place, and culture that support them. While vocational personality deals with this self-organization, the second component of career construction theory, namely career adaptability, deals with self-regulation and self-extension of personality into the social environment.

## Career Adaptability

Career construction theory conceptualizes development as driven by adaptation to an environment and integration into the community. From this perspective, an occupation is a mechanism of social integration, one that offers a strategy for sustaining oneself in society. Careers are constructed by adaptive strategies that implement an individual's personality in an occupational role. This adaptation brings inner needs and outer opportunities into harmony, with the harmonics of a good fit amplifying in present activity the individual's past preoccupations and future aspirations. Adaptation involves adjusting to occupational changes that include mastering vocational development tasks, dealing with work traumas, and negotiating job transitions. Career construction theory views adaptation to these changes as fostered by five principal types of coping behaviors: orientation, exploration, establishment, management, and disengagement. These constructive activities form a cycle of adaptation that is periodically repeated as the individual navigates new transitions.

Career adaptability denotes an individual's readiness and resources for handling current and anticipated tasks, transitions, and traumas in his or her occupational roles that to some degree large or small alter his or her social integration. The adaptability dimensions of readiness and resources shape self-extension into the social environment because they condition the actual coping behaviors that constitute orientation, exploration, establishment, management, and disengagement. They function as self-regulation strategies that govern how individuals engage the developmental tasks imposed by the communities with whom they co-construct their careers.

In considering the dimensions of psychosocial adaptability, career construction theory highlights a set of specific attitudes, beliefs, and competencies—the ABCs of career construction—that regulate the coping behaviors for implementing vocational self-concepts into occupational roles. The ABCs are grouped into four dimensions of adaptability: concern, control, curiosity, and confidence. According to this scheme, the adaptive individual is conceptualized as (a) becoming concerned about the vocational future, (b) increasing control over that future, (c) displaying curiosity by exploring possible selves and future scenarios, and (d) strengthening the confidence to pursue one's aspirations.

## Life Themes

The self-organization of personality and its adaptive self-extension into the community produces a self-defining story. The essential meaning of career and the dynamics of its construction are revealed in these self-defining stories about the tasks, transitions, and traumas an individual has faced. Unlike the RIASEC types and adaptability dimensions, career stories fully contextualize the self in time, place, and role and express the uniqueness of an individual. Furthermore, the separate career stories told by an individual are unified by integrative themes that make whole the individual's complex and contradictory experiences by inscribing them with a meaningful coherence and long-term continuity. The theme does not summarize past experiences; rather, it inscribes them with a sense of purpose that provides meaningful coherence and long-term continuity.

Stories are accounts that constitute the self. People talk themselves into existence as they describe what they like and what they are like. From this perspective on the self, occupational preferences express self-conceptualizations in vocational terminology. Accordingly, entering an occupation is viewed as an attempt to implement a self-concept and the work itself manifests the self-concept, giving it substance and story. Thus work provides a context for human development and an important location in each individual's life, a place that matters.

In listening for the theme in career stories, counselors can become disoriented by the numerous particulars of a life. To prevent this confusion, career construction theory suggests that career practitioners and researchers concentrate on the motif, or controlling passion, that arranges the separate stories into a coherent whole. Arranging the actions and incidents randomly portrayed in career stories into a plot can be done in many ways. Career construction theory proposes for this purpose using the narrative paradigm to organize biographical thinking. This perspective for understanding a story and illuminating a life highlights the challenge of the client's life, one that he or she cannot ignore or go around. Career construction theory, applying its narrative paradigm, assumes that the archetypal theme of career construction involves using work to turn preoccupation into occupation, thereby resolving the challenge. Simply stated, careers are constructed as individuals, using adaptability coping strategies, turn their personal preoccupations into

public occupations. The researcher or counselor listens to the stories to learn how the individual has used work to turn a personal symptom into a public strength and then even into a social contribution. Using the narrative paradigm as a biographical organizer enables the listener to draw out the silk thread of a life theme from the cocoon of autobiographical stories.

## Counseling for Career Construction

Counseling for career construction begins with an interview that poses a uniform set of questions to a client. The Career Style Interview elicits self-defining stories that enable counselors to identify and appreciate the thematic unity in a client's life. In addition to revealing the life theme that threads through the client's life, data from a Career Style Interview also manifest the client's vocational personality and substantiate adaptive strategies. Responding to the interview questions enables a client to hear his or her own story in community. The counselor helps clients to increase the narratability of their stories and to relate their life themes to the choices that they must now make. In discussing the alternative choices and how each one might advance the client's story, the counselor retells the story in a manner designed to increase the client's career adaptability, consider what is at stake, and identify occupations that can be used to write the next chapter in their story. Reflecting on and retelling their stories encourage clients to understand how they can use work to become more whole and participate fully in a work role that matters to both them and their community.

## CAREER COUNSELING

---

Most entries in this encyclopedia provide detailed treatments of precise topics. This entry illuminates the relations among these topics. It summarizes the development of career counseling, the most widely used career counseling interventions, the typical settings in which career counseling occurs, important differences among clients who seek career counseling services, the focal issues examined in career counseling, and the career counseling process. The entries appearing in this encyclopedia describe these topics in greater detail.

## Development of Career Counseling

The theoretical underpinnings of career counseling were first recorded around 360 B.C. when Plato observed in *The Republic* that different jobs require different types of workers for optimal performance. Today we regard this as obvious; the jobs of elementary school teacher, truck driver, opera singer, and accountant each require a different set of skills and interests.

Frank Parsons formalized this theory of the relation between people and jobs in the late 19th century. He wrote that effective career placement requires knowledge of the special talents of the worker, the requirements of various occupations, and the relations between these sets of knowledge. Over time Parsons's ideas have been codified into the person–environment fit model and trait and factor counseling. The overlapping disciplines of counseling psychology, vocational psychology, and career counseling emerged from this beginning.

Three crises, World Wars I and II and the Great Depression, helped shape career counseling. Prior to

World War I, French scholars Alfred Binet and Theodore Simon developed a test to measure cognitive ability. Their work paved the way for modern intelligence tests. Entry into World War I suddenly confronted the United States with the need to place hundreds of thousands of workers into suitable jobs. Using the Binet-Simon approach as a starting point, the U.S. Army developed a series of tests (e.g., the Army Alpha and Army Beta) to measure cognitive aptitudes. Scores of these tests were used to place military recruits into suitable jobs. This work developed and validated a model of vocational placement that has been a key component of career counseling for over 90 years.

The Great Depression focused attention on the nation's workforce and provided another stimulus to the development of career counseling. Under the leadership of Donald G. Paterson at the University of Minnesota, the Minnesota Employment Stabilization Research Institute (MESRI) undertook a decade of research on the optimal relation of workers to jobs. MESRI research demonstrated that workers perform better and are less likely to quit or be terminated when placed in occupations that match their interests and aptitudes. The MESRI also developed an extensive library of aptitude tests for use in job placement. MESRI research demonstrated unequivocally that skilled career counseling using a trait-and-factor approach produces beneficial results.

The entry of the United States into World War II again created a need to assign millions of workers to jobs in an efficient manner. The career counseling procedures and instruments developed and validated by the MESRI were applied in the most massive application of career counseling in history.

Following the war, the GI Bill enabled veterans to enter colleges and universities in unprecedented numbers. This created a strong need for career counseling services in those institutions. An even larger number of veterans sought civilian jobs. This created a demand for career counseling services for civilians and stimulated the development of the United States Employment Service.

Clinical psychology was a well-established specialty for treating the mentally ill by the end of World War II. Insightful leaders such as University of Minnesota psychologist John G. Darley recognized that normal individuals sometimes need assistance in dealing with problems confronting them in daily life. Clinical psychologists were ill prepared to provide this assistance, but that is the type of assistance career

counseling personnel had been providing. The contemporary specialty of counseling psychology is an outgrowth of the MESRI research, military experience in vocational placement, and Darley's recognition of healthy individuals' needs for developmentally oriented services.

As the United States became more affluent during the 1950s and 1960s, two social movements furthered the development of career counseling. Early 20th-century generations experienced the strife and deprivation of two world wars and the Great Depression, but the baby boom generation experienced a time of relative affluence and tranquility. The earlier generations' survival concerns were replaced by the baby boomers' desire for an occupation that would enhance their quality of life and contribute to a better world. Established workers also began to consider a midlife career change to a more meaningful occupation. Workers who in earlier times would have unquestioningly followed in their parents' footsteps or taken a job that satisfied their basic survival needs now turned to career counseling for assistance in achieving these goals.

At the same time, leaders like Mohandas Gandhi, Martin Luther King, and Betty Friedan were exposing the glaring inconsistency between the public endorsement of equality and the harsh realities of colonialism, racism, and sexism. Minority group members, women, and immigrants whose parents had few choices were now confronted with increased opportunities, and many turned to career counseling for help in making informed decisions.

The last 2 decades have seen a growing concern about the aging American workforce. In earlier decades relatively few workers achieved retirement age, and most who did died shortly after retirement. Today a steadily increasing proportion of the workforce lives for a decade or more after retirement. The importance of maximizing the efficiency of the workforce is steadily increasing as the proportion of the population in the workforce decreases. Industrial nations cannot afford to ignore the potential contributions of any segment of their workforce. Handicapped and disadvantaged individuals, Native Americans, displaced workers needing retraining, people having limited English proficiency, single parents, criminal offenders, and chronically unemployed workers—the contributions of all are critical to the health of the nation's economy. All must receive the assistance they need to make the most of the opportunities available. The need for skillful career counseling is as great as at any time in history.

## Career Counseling Interventions

Modern career counseling is a multifaceted specialty that provides a rich array of services. This section provides a synopsis of frequently used career interventions: individual counseling, group counseling, computer-based interventions, and career education. It is important to understand, however, that basic activities such as assessing interests, values, and aptitudes; providing occupational and college major information; and providing instruction in job search skills are included in each of these types of counseling interventions.

### *Individual Counseling*

Individual career counseling involves a professional counselor working in a one-to-one relationship with a single client. The objectives of individual counseling may focus on helping clients increase their self-knowledge, decision-making skills, or knowledge of occupational opportunities and the world of work. Often this involves the administration and interpretation of psychological tests and the use of reference sources to obtain detailed occupational information. Individual counseling may also involve other activities under the supervision and coordination of a psychologist. For example, clients may use computer guidance systems such as the System of Interactive Guidance Information (SIGI), may participate in workshops on topics such as study skills or time management, and may participate in structured groups that deal with issues such as assertion training, resume development, or job interviews.

Individual counseling is a desired and important component of effective career counseling. Several studies have shown computer-assisted guidance systems to be effective in enhancing career outcomes. However, clients prefer to use them in conjunction with individual career counseling, and their use in combination with individual counseling is more effective than their use alone.

### *Group Counseling*

Group counseling differs from individual counseling in one important respect; group members learn from each other in addition to learning from their interactions with the counselor. This can be particularly valuable to individuals who are early in their career exploration and lack career-related experience and information.

Group career counseling takes a variety of forms. Career development groups include most of the components found in individual career counseling, and they have similar objectives. Group participants typically take tests and participate in a group discussion of their test results. In addition, they may be assigned to complete a computer-based activity, prepare a resume, complete a homework assignment, or interview a potential employer or a person employed in a career of interest. Clients complete these activities outside the group and discuss their experiences during a group meeting.

Structured group interventions are more narrowly focused on a specific issue. The goals of structured groups are limited only by the needs of clients and the imagination of psychologists. For example, structured groups are commonly offered to teach assertiveness skills, resume preparation, time management, study skills, and interviewing skills. Sensitivity groups focus on interpersonal topics such as sexism, racism, and other workplace behaviors.

### *Electronic Media*

Computer-based career counseling modules are delivered via computer or online via the Internet. Computer-based career assessment inventories are now common. Among the most widely used online career interest inventories are the Strong Interest Inventory, the Self-Directed Search, the Kuder Interest Inventory and Career Planning System, the ACT's Interest Inventory (UNIACT), and the Interest Profiler found in the U.S. Department of Labor's Occupational Information Network (O\*NET). The online administration of aptitude tests is increasing and some, such as the Graduate Records Examination (GRE), now require special arrangements for any other than an online administration.

Career information is also widely available via electronic media. Meta-analyses reveal that access to accurate occupational information is among the most important predictors of a positive outcome. The O\*NET contains a comprehensive set of databases that permit on-line searches of occupational information using criteria such as interests, values, and employment growth. ACT and the College Board maintain free sites that permit users to search for a college using criteria such as admissions requirements, tuition costs, and geographic location.

Computer-based guidance systems now offer the full range of career guidance services. DISCOVER and SIGI house instruments for measuring interests,

abilities and values. Also included are databases containing detailed information about occupations (both military and civilian), majors (ranging from short technical training programs to graduate programs), colleges and universities, and financial aid. Individuals can complete a DISCOVER or SIGI assessment tool to learn about themselves; use the programs' databases to relate their scores to their choices of a school, college major, or career field; and then access information about the education, skills, and background required for their selected options.

Psychologists now provide online career counseling services using online chat, videoconferencing, voice over Internet protocol (VOIP or Internet phone), e-mail, and weblogs. These options make career counseling services available to people who might not otherwise have access to counseling (e.g., homebound individuals and those living in areas not serviced by professionals). Some caution is advisable because these approaches to service delivery have not yet been evaluated sufficiently. There is reason for optimism, however, because preliminary evidence suggests that e-mail, chat, and videoconferencing can provide effective career counseling services for some clients.

### **Career Education**

Career education refers to an organized program of instruction designed to increase vocational self-knowledge, provide occupational information, teach effective decision-making skills, and improve the individual's ability to deal with life transitions. Ideally, children will be introduced to career education during their early years and have continued exposure to career education as they progress through the educational system. Critical considerations in the design of career education for children are the learner's developmental stage, knowledge of the types of activities that are appropriate for learners at each developmental stage, and an understanding of the intended outcomes.

Exposure to career education continues to be important after the completion of formal education. The last 3 decades have seen a shift away from the view of employment as a lifelong commitment between worker and employer. Workers are now regarded more as independent contractors who move from job to job across their work life. Career education for mature workers helps them develop and maintain transferable skills that are useful in multiple employment contexts. Mature workers continue their

career education by enrolling in continuing education programs and by maintaining a lifelong commitment to learning.

## **Career Counseling Settings**

Career counseling is widely available in colleges and universities; in the United States many offer career counseling services for faculty and staff members in addition to students. Career counseling services also are available in a variety of alternative settings in contemporary American society. This section describes career counseling in schools, colleges and universities, businesses, nonprofit and professional organizations, and private practice settings.

### **Schools**

Career counseling in schools begins in the elementary school years and continues through high school graduation. The purpose, particularly in the elementary and middle school years, is to inform students about career-related issues and to spark the career development process. Successful activities are consistent with the students' vocational maturity (i.e., their stage in the career development process). Most elementary school students have not yet begun to think realistically about career issues; career education initiates the transition from career fantasies (i.e., being a ballerina or baseball player) to realistic career planning.

Much of the early career-related instruction appears in examples in assigned reading materials (e.g., readers and social studies books). As students progress through the elementary grades, career education activities become more common. Many of these take the form of special assignments or modules introduced by the teacher. Other career education activities include career days and speakers who talk about career-related topics.

The pace of career development varies greatly as adolescents progress through the middle school and high school years. Many can benefit from group activities such as workshops, but others require more specialized attention such as that provided by group counseling or individual counseling. The objectives during the middle school years are to broaden the range of options students consider and to provide the information they need to think realistically about careers.

During high school, students begin to plan for their entry into the workforce or to attend a college or university. Individual counseling, group counseling, and

structured workshops are more common during these years. It is only at this age that most students begin to be able to relate career issues to their personal situation. The goals are to sensitize students to the vocational significance of their personal values, interests, and skills and to provide information about the demands and benefits of alternative career options.

### ***Colleges and Universities***

For most students, the entry into college demarks the beginning of their ability to act upon career choices. Although many have given considerable thought to their career plans, their ability to explore their ideas in a meaningful way has been constrained by their age, dependence on their family, and limited work experience and high school curricular offerings. Thus, many enter higher education with an understanding of the importance of career choice and with feelings of anxiety regarding their relative lack of progress.

Most college students engage in a period of exploration during which they try out various courses, part-time jobs, and volunteer activities to learn more about themselves and their career options. Often they recognize a need for increased personal understanding of their interests, values, and aptitudes. The need for greater self-knowledge may also involve gaining a more mature understanding of their own unique circumstances as a woman, racial minority group member, disabled individual, or gay, lesbian, or bisexual person. Older adults returning to college after an absence from school often face additional issues such as work–family conflicts, stress, and age discrimination.

A wide variety of career services are available in campus settings, including individual and group counseling, structured workshops, internships, student work opportunities, and assistance with job placement. In aggregate, these services strive to achieve the goals of Frank Parsons's model: helping students learn about themselves, the world of work and the relation between the two sets of knowledge.

### ***Organizations***

Among the earliest organizations to provide career counseling services were the corporations that emerged with the industrial revolution. Until recent years the primary focus of these organizations was employee selection and individual career advancement (often referred to as career management).

Corporations began to offer a wider range of services in the late 1980s, and many now offer a program of career counseling services.

Government agencies such as the military, rehabilitation agencies, and correctional facilities also provide career counseling services. Career counseling on military bases tends to emphasize the transition from a military specialty to a civilian occupation. Rehabilitation counseling helps people identify suitable training and employment options so that they can become self-supporting. The focus in correctional and mental health facilities is on helping clients develop work attitudes, behaviors, and marketable skills that will permit them to secure and maintain employment following their discharge.

Many organizations employ staff members (often in their human resources department) to provide career services. Specialists employed as independent contractors may supplement the routine services by providing specialized services such as psychological assessment and work evaluations. Other organizations contract with independent professionals or corporations (e.g., an employee assistance firm) for career counseling services.

### ***Private Practice***

Until recently there was little opportunity for career counselors to work exclusively in private practices. Free career counseling is available to most individuals through schools, colleges and universities, services organizations (e.g., B'nai Brith and Big Brothers and Big Sisters of America) and government agencies (e.g., the United States Employment Service, the Rehabilitation Services Administration, and the military). However, expansion of the range of career services offered by corporations in the late 1980s increased the opportunities for psychologists in private practice to specialize in career counseling. Organizations often find that contracting with private practitioners is cost-effective because career services can be purchased on an as-needed basis.

The career counseling services most frequently provided by private practitioners are those specialized or time-intensive services that are not cost-effective to provide in house. These include individual counseling, psychological assessment, assistance with career decision making and coaching, and career management.

Private practitioners also have organizations as their clients. Their functions in these arrangements often include assistance with staffing decisions

(e.g., evaluating candidates for employment or promotion), the development of succession plans and programs, assisting employees in dual-career and dual-partner relationships with their career transitions and career search, and outplacement. Organizations often seek the assistance of an independent contractor when issues such as sexual harassment, sexism, or racism require attention.

### **Career Counseling Clients**

Psychologists and counselors who provide counseling services recognize and value the uniqueness of each client. They approach their counseling interactions with clients without preconceived notions, but they also recognize that all people are influenced by their cultural and social experiences. This section briefly reviews some of the critical issues that psychologists and counselors consider when providing career counseling services to selected groups of clients.

#### ***Work-Bound Youth***

Work-bound youth have limited life and work experience to draw upon in making life-shaping career decisions. To become successful employees, they must possess basic academic (e.g., reading, writing, and mathematics) and cognitive (e.g., decision-making and problem-solving) and social and personal (e.g., conscientiousness and self-management) skills. Psychologists and counselors counseling work-bound youth formulate an approach for career counseling based on their evaluation of the client's vocational maturity and proficiency in these domains. The choices made by these youngsters are the initial steps in their career, so career counselors help them make decisions that will maintain their future options rather than foreclose future possibilities.

#### ***Adults in Transition***

The cohort of adults making career transitions is varied because any passage that causes a change in status (e.g., marriage, birth of a child, death of a loved one, termination from employment, and decision to retire) can trigger a career transition. Transitions such as school-to-work and a change in job title and responsibilities can be anticipated. This permits the development of a strategic plan that allows some control over the timing, pace, and details of the transition.

Nevertheless, anticipated transitions require some changes in behavior and relationships, and they involve both losses and gains.

Unanticipated transitions catch people by surprise. They can result from events (e.g., downsizing and health issues) or planned events that fail to occur. Unanticipated transitions allow little or no time to develop plans for minimizing negative consequences, and they often cause a sense of personal crisis.

#### ***Clients With Disabilities***

Disabilities can be classified as physical, psychiatric, or cognitive in nature. Physical disabilities limit people's ability to perform the full range of typical motor functions. They can result from congenital conditions, physical injuries, or progressive conditions such as diabetes. The environment is an important factor in determining the effects of a condition. For example, the inability to stand is not a limitation in most situations where keyboarding is performed because most people perform that activity while sitting.

Psychiatric disabilities affect the person's ability to reason and to deal successfully with typical life events. Cognitive disabilities affect the individual's problem-solving and decision-making abilities. Contrary to stereotypes, people's ability to perform many occupations is unaffected by these disabilities.

Psychologists and counselors working with individuals having a disability evaluate both the nature of the disability and the individual's adjustment to the disability. Adjustment takes time, and people also differ in their ability to accept changes in their status. Clients who have not yet made a realistic adjustment to their present status typically require different counseling services than those who have adjusted to their status and are committed to making the best of their life.

An individual's adjustment to a disability may vary over time. Conditions that require careful attention to a medical or physical regimen are susceptible to variations in adjustment. For example, some people with a psychiatric disability may function successfully for a period of time, but then relapse because they discontinue their medication.

Another consideration is whether the disability is stable or progressive. Stable disabilities allow the counselor and client to make career plans based on the client's present status. Progressive conditions require career plans that anticipate the progression of the disability.

Regardless of these differences, however, psychologists and counselors avoid making the disability the focus of their attention. The goal of counseling is to identify vocational options that provide an optimal fit for the client. This determination is made in the context of the Americans with Disability Act (ADA), which requires employers to make reasonable accommodations to enable persons with disabilities to perform jobs successfully. Psychologists and counselors help clients understand their rights under the law, identify the accommodations that will allow them to perform desired occupations successfully, and help them practice constructive ways to communicate this information to employers and prospective employers.

### ***Ethnically and Culturally Diverse Clients***

Differences attributable to cultural and social experiences are universal. For example, collectivist cultures endorse values and behaviors that differ from those preferred by individualist cultures. Important cultural differences exist even among groups many unthinkingly regard as homogeneous: Euro-Americans who trace their ancestry to Scandinavian countries (e.g., Danes, Swedes, and Norwegians), the British Isles (e.g., Irish, English, Scots, and Welsh), and Germanic countries (e.g., Dutch, Germans, and Austrians). Some groups (e.g., Irish and German) have suffered from pervasive discrimination in recent memory, and others are still targets of discrimination (e.g., African Americans and Native Americans). Some groups are still targets of negative stereotypes (e.g., Jewish, Irish, homosexual, and Native American individuals).

Psychologists and counselors avoid stereotyping, but they recognize that members of social, gender, and ethnic groups are likely to have had common experiences and to share similar views of the world. Psychologists and counselors attempt to understand and respect the influence of their client's cultural heritage. The following sections describe factors psychologists consider when providing career counseling to individuals from selected segments of American society.

#### **African Americans**

Understanding the African American culture in the context of White American culture is critical to success in counseling African Americans. Developing an understanding of the differences in the way African

Americans experience American society is necessary to work effectively with them. Variables that are important include the client's racial identity development, social network, role models, family influences, and perception of the barriers that racism and lack of economic resources impose to reaching their career goals.

#### **Asian Americans**

The stereotype that Asian Americans are a model minority is as harmful as the more negative stereotypes attached to other groups. Asian Americans' reticence to disclose personal problems to avoid "loss of face" may account in part for this stereotypic impression. Nevertheless, this stereotype suggests that Asian Americans need less attention than other segments of American society. That view encourages neglect, and it contributes to the fact that relatively little is known about Asian Americans' career development and career behavior.

Asian Americans' career interests, values, and vocational behavior tend to differ from those of the typical Euro-American. For example, parental influence plays a greater role in their career decision making. Asian Americans rely more heavily on collectivist approaches to work-related tasks, a difference that is sometimes interpreted as reflecting insecurity and a lack of leadership qualities. From an Asian American perspective, however, these behaviors reflect their cultural emphasis on collectivist approaches to problem solving.

#### **Latinos**

Latinos form a diverse group of individuals whose ancestry derives from Spanish-speaking countries in Central America, South America, and the Caribbean. As a group, their career aspirations are as high as those of other segments of American society, but their expectations to achieve their aspirations are lower than those of other groups. This lack of confidence is attributable in part to a lack of self-efficacy beliefs and to their perception of barriers to their career goals. These factors cause Latinos to eliminate desirable career options from consideration.

Latinos value family strongly; many place greater importance on being a part of the family unit than on meeting their individual needs. Latinos are likely to make career decisions in consultation with family

members. They give strong consideration to the effects of their choices on their family, and they may sacrifice personal needs to the family's welfare.

Latinos are concentrated in the working class and in working-class neighborhoods. They are underrepresented in many desirable high-paying and high-status occupations. These factors limit the occupations to which they are exposed and influence the quality of the education they receive. Many obtain a less than average education from the public school system and lack the resources to pursue additional education or other career training. In addition, discrimination may pose a barrier to considering some career options.

### **Native Americans**

Success in pursuing educational and career objectives requires Native Americans to balance their commitment to their traditional culture with the need to become comfortable in the dominant Euro-American culture. This challenge is unique to Native Americans, and it calls into question the cultural validity of some mainstream career development constructs such as career maturity.

Native Americans often live in rural locations in impoverished communities. They have the highest unemployment rate and the lowest rate of academic achievement among minority groups in America. Many Native American tribes emphasize a sense of physical place and view their relation to the environment differently than Euro-Americans. Many also emphasize collectivist values, and they regard competition less favorably than Euro-Americans. They value the advancement of the social unit rather than efforts by a single individual to stand out above the rest.

These factors influence Native Americans' approach to career development. For example, they involve family and tribe in their career decision making and in the career development process. Career counseling that considers the culture, context, and constructions of the Native American culture may be more successful than counseling from the perspective of the majority culture. It may be important to include family members and even tribal leaders in the career counseling process.

### **Immigrants**

Although many immigrants share a racial heritage with African Americans, Asian Americans, or Latinos,

they differ in that they are new to the country in which they reside. They may not speak the dominant language, may not have a locally accessible network of friends or relatives, and may not be aware of the resources available to help with their career and related issues. Regardless of their educational level and technical training, administrative barriers such as work permits and licensing requirements may limit the types of positions they can hold. Counselors may need to assist immigrant clients in dealing with the bureaucratic requirements that impose barriers to career development.

People immigrate to a new country for a variety of reasons including better economic prospects, political persecution, and a natural disaster. In some instances, families arrive intact; while in other instances, immigrants arrive alone. Many immigrate legally, but approximately half of the immigrants enter the United States illegally. These factors influence immigrants' willingness and ability to benefit from career counseling.

In addition to discrimination, language skills, and administrative barriers, subtle factors also influence the career development of immigrants. Career counselors may need to deal with personal issues such as loss of power and status, changes in role appropriate behavior, and feelings of impotence from loss of ability to provide for the family. Interpersonal styles that are accepted in the immigrant's native culture may be considered inappropriate in the United States. Immigrants from male dominant cultures may find that their values and role expectations are inconsistent with Euro-American values. Females from these cultures may feel uncomfortable making decisions without the permission of the significant males in their lives. Individuals from collectivist societies may need to include their entire family in the career decision-making process.

### **Gay and Lesbian Clients**

In contrast to other segments of American society, gay men and lesbians must contend with the reality that discrimination against them is legal and institutionalized. Those who are employed often have to contend with discriminatory institutional policies (e.g., limits in healthcare coverage) and a workplace climate that is unwelcoming or hostile. Some segments of society even regard such discrimination as a sign of the moral superiority of the person practicing the discrimination.

Because discrimination against them is legal, many homosexual persons feel threatened and are reluctant to participate openly in psychological research. As a consequence, information about their vocational interests, career aspirations, and other aspects of their career development is not readily available. For example, stereotypes suggest that gay men and lesbians tend to value gender nontraditional occupations, but there is little scientific research to illuminate this possibility. It is not clear whether homosexual individuals possess genuinely nontraditional interests and aspirations, or whether they are attracted to occupations they perceive to be more accepting of homosexual individuals.

Career counselors take care to ensure that their personal values do not interfere with their work with homosexual clients. They refrain from imposing their values on the client and remain sensitive to their clients' needs, values, and aspirations. They are comfortable discussing their client's sexual identity. They help their clients consider how negative stereotypes and covert and overt discrimination may affect their career choices and career development, how open their clients plan to be regarding their sexual identity, and the potential consequences of that decision.

### **Career Counseling Issues**

Psychologists and counselors place no artificial limits on the issues clients can raise in career counseling. Clients often come to career counseling wanting help with a specific issue and intending to talk only about a limited range of topics, but achieving a beneficial outcome often requires the examination of a wide range of issues and topics. For example, unhappiness at work can have negative consequences at home and vice versa. Resolving problems that involve work often require dealing with problems in other aspects of life. Every issue discussed in this volume of the *Encyclopedia of Counseling* is relevant for discussion in career counseling.

### **Career Counseling Process**

Career and personal counseling evolved from the job placement and vocational guidance models that psychologists developed during the first half of the 20th century, and career and personal counselors use many of the same helping skills. Although the external appearance of counselor–client interactions may

differ across these specialties, the underlying elements that account for much of the success of the counseling interaction are the same. Both specialties require proficiency in basic interviewing and psychological assessment skills.

Success in career counseling depends upon the skillful use of active listening skills and the development of a therapeutic counselor–client relationship. This involves establishing an emotional bond between the counselor and client based on mutual respect and trust and reaching an agreement on the goals of therapy and the tasks that will be undertaken to achieve those goals. Development of the therapeutic relationship begins in the first interview and continues throughout the course of counseling.

Success in career counseling also depends upon the skillful use of assessment procedures to assist the client's self-exploration. An individualized interpretation of the test results and knowledgeable assistance in relating the test results to occupational information leads to the identification of a narrowed range of potential occupational alternatives for the client to consider. This enables the client to gather more detailed information about those occupations and ultimately to make informed career decisions.

Throughout the career counseling process psychologists and counselors provide emotional support, help their clients establish goals, and provide assistance in developing problem-solving and decision-making skills when needed. Many career counselors also help their clients develop resumes, interviewing skills, job search skills, and social support and career networks.

### **Conclusion**

Career counseling theory and practice is an effective psychological specialty that has benefited from over 90 years of innovation and experimentation. Meta-analyses of decades of research reveal that career interventions produce measurable benefits. Individual career counseling, structured career counseling groups, career workshops, and career education are all effective interventions that are useful for helping clients explore options and make career decisions. Nevertheless, efforts continue to identify even more effective career counseling interventions that can be used to assist an increasingly diverse clientele.

## CAREER COUNSELING, AFRICAN AMERICANS

---

Early in the 21st century there continues to be economic disparities between racial ethnic groups. The latest census indicated that Asian American couples had the highest average annual earnings at about \$57,500 per year, followed by Caucasian Americans at roughly \$49,000, then Hispanics with \$39,241, and finally African Americans at about \$30,000 per year. There are three times as many African American males imprisoned as there are in college. In the state of Tennessee, 80% of the people living in poverty are women and children, and African American women are over represented in those numbers. While African American youths are closing the high school graduation rate between them and White American youths, African Americans still tend to be overrepresented in low-pay/low-skill jobs and underrepresented in high-skill and professional jobs, although African American youths have equivalent career aspirations as those of their White counterparts.

Given these continuing seemingly intractable facts one wonders how a career counselor can make a difference. Certainly many authors have maintained that traditional career counseling theories do not easily fit this population. Although social cognitive career counseling has shown some promise of being broad enough to include African Americans, some scholars maintain that perhaps the entire field of career counseling needs to be refocused for some populations away from career decision making and toward theories of work. A career implies a directional succession of jobs or work that is driven by choice and intentionality. Individuals who are dealing with poverty, the prison system, and other societal barriers are often working at any job that meets their survival and basic human needs versus working toward a career. It could be, however, that even in these situations an appropriate career development theory coupled with an effective assessment method and intervention could be useful.

### **Factors That Influence Career Development**

Theorists have proposed that an individual's career choice is affected by layers of interacting factors that can be depicted as a set of expanding circles. At the core of the circles are biological factors. They suggest that our genes influence our predispositions to certain types of behaviors, emotions, and psychological traits that may tend to lead us to one type of career or job as opposed to another. It could be that as we continue to understand the human genome those predilections will become clearer.

Next are gender factors. In the United States significantly more males than females are found in realistic occupations, and more females are in the social occupations as defined by the Holland Hexagon. Society seems to begin to push boys and girls toward different activities and careers when they are very young.

The theorists next propose that careers are influenced by families and the families' life circumstances. It is not unusual to see families in which several generations are doctors, politicians, or involved in the criminal justice system. An African American male child with a parent in the criminal justice system is over 50% more likely to also be involved with that system. It is very difficult for African Americans born into poverty to rise out of that poverty. If the parents,

however, push education, then the child has a greater chance of entering the middle class. African American parents do have a great deal of influence on a child's interest in education.

Racial and ethnic subgroups are theorized to have an impact on career development and career choices of the groups' members. Although race and ethnicities are often viewed as social constructions, some work suggests that there is a racial identity development phenomenon and that individual behavior and even approaches to career decision making is influenced by that identity development process. Even in integrated settings racial and ethnic groups often divide along racial lines. In her book, *My Freshman Year*, Rebekah Nathan noted that in the dining hall of a large predominantly White university the Black students sat with each other as did the Whites, the Asians, and so on. Even though some authors have stated that today's college students, called Millennials, are more desegregated than ever, it was among this group that Nathan noted her findings. So it is reasonable to assume that the people with whom one spends time are likely to influence one's career development and career decisions.

Finally, the dominant or majority group has an impact on career and job outcomes. Structural factors, perceptions, and barriers can determine whether or not one can rise in the corporate culture or even get in the door. It is in this circle that sexism, racism, or the other isms exist and help determine career choice or lack thereof.

It is important for a career counselor to explore all five of the interacting circles if he or she is to have a meaningful interaction with an African American individual. In order to explore the factors in the circles one needs good assessment instruments. Two practical instruments described next can be used in applied settings.

### **Cultural Assessments**

It is important for the counselor to develop some understanding about African Americans if the counselor is to offer an effective intervention. It is just as important for the client to gain some clarity about his or her career questions. To help the counselor and client, researchers developed the Multicultural Career Counseling Checklist and the Client Career Counseling Checklist.

The Multicultural Career Counseling Checklist encourages counselors to make sure they are familiar with African American culture in context with the majority White American culture. Such understanding includes familiarity with class, family, gender, and structural factors. The counselor is also directed to understand personal racial identity development and the racial identity development of the client.

The Career Counseling Checklist is given to clients prior to any interventions. Clients are asked to think about matters that include abilities, cultural issues, career knowledge and behaviors, self-confidence, secret daydreams, and so on. The counselor can use the information to establish an appropriate intervention, though the counselor may still be unsure where to begin.

### Steps to Multicultural Career Assessment

Researchers recommend that counselors begin with cultural variables, including worldviews, racial identity development, and structural factors such as barriers imposed by class or racism. Sometimes when these barriers are explored, the career questions are answered at that step.

Other times one must move to gender variables including asking African American men and women about how they were socialized in their respective gender roles, work-home salience, and even extended family expectations. The counselor may then need to explore the client's level of confidence in self, ability to do the job, or even ability to overcome social and structural barriers. It is only after all the above areas are explored that moving to traditional assessment instruments like the Strong Interest Inventory or interventions like a career shadowing experience is recommended.

If a counselor will explore the cultural factors that influence career development, prepare him- or herself and the client through a thorough cultural assessment, and follow the steps to multicultural career assessment, then the intervention is likely to be more effective whether one is helping a client prepare for a job or a career.

## CAREER COUNSELING, ASIAN AMERICANS

---

It has been repeatedly observed that the current literature has limited information on the development and career behaviors of Asian Americans. For example, Asian Americans and Pacific Islanders are more likely to request information about career issues and are also more likely than other ethnic groups to use college career information centers. Since Asian Americans are

the fastest-growing minority group, it means that professionals will need culturally sensitive career theories and interventions in order to be culturally effective with Asian Americans. Ultimately, this will translate to culturally informed career assessments, counseling, and interventions for this population. Synthesizing career practice with suitable theories will help professionals meet the needs of Asian Americans within an arena that is considered important to their well-being and functioning.

### **Levels of Analysis**

There are two levels of analysis in the review of career counseling among Asian Americans: (a) an individual level of analysis that involves issues such as career interest, values, choices, and behaviors; and (b) a group and societal level of analysis that consists of the effects of macrolevel processes such as family influences, occupational stereotyping, occupational discrimination, occupational mobility, and occupational segregation. All these factors have certain implications for career counseling with Asian Americans.

#### ***Individual Level of Analysis***

##### **Career Interests**

When counseling Asian Americans regarding career issues, it is important to consider the client's career interests. Over the past 20 years only a handful of studies have highlighted the career interest patterns among Asian Americans. For example, in most studies where Chinese American males were compared to other ethnic males, they demonstrated a greater interest in the occupational fields of physical science, skilled technical trades, and business. These males also showed lower levels of interest in areas associated with social service and welfare, sales or business contact, and verbal-linguistic occupations (social). There are other recent studies that show how Asian Americans display career interests that are consistent with realistic and investigative domains. Another way to examine career interests among Asian Americans is to investigate the courses and majors students choose. Data from the National Science Foundation suggest that Asian Americans are twice as likely as White students to have an interest in a science field, and this interest is usually paralleled by high educational aspirations (e.g., aspirations to obtain a doctorate or medical degree).

##### **Occupational Values**

Career counselors have to attend to the occupational values of Asian Americans, some of which are money, task satisfaction, prestige in career, and service dedication. When compared to European Americans, Asian Americans placed a greater emphasis on the extrinsic and security values on the occupational values scales and less of an emphasis on values such as self-expression, power, and social factors. This emphasis on extrinsic factors such as security, money, and service to others can be traced back to Asian cultural importance on issues such as pragmatism, collective styles in decision making, and the influences of the processes of acculturation and the experiences of immigration.

##### **Career Choices**

It would appear that career choices would be a direct reflection of career interests. However, there are a host of factors that influence career choices among Asian Americans regardless of their career interests. For example, Asian Americans place a high value on parental involvement in their career-related choices, to the point that higher parental involvement can predict more traditional career choices (i.e., science or technology career paths). Studies have shown that Asian American parents are more likely to exert direct influences on their children's career choices and aspirations as a result of fear of their children having to undergo the effects of discrimination. Other influential factors include Asian values of respecting authority and submitting to the wisdom of elderly and family, level of acculturation, family background, and self-efficacy. These factors have yet to be empirically tested, but they suggest that it is imperative to include family in the career counseling process.

##### **Career Behaviors**

Asian Americans display a higher level of dependent type decision-making styles than do Whites, a pattern that could be attributed to the value placed on collectivism. However, during counseling this interdependence cannot be confused with dependence, which can be equated to a lack of independence or low career maturity among Asian Americans. Research has highlighted three main personality traits associated with career behaviors among Asian Americans: locus

of control (less autonomous, more dependent, and more obedient to authority), social anxiety (more emotionally withdrawn, socially isolated, and verbally inhibited), and intolerance of ambiguity (valued practical applications and were more socially conforming).

### ***Group and Societal Level of Analysis***

#### **Family Influences**

A few studies have been conducted confirming the existence of the significant and central role families have in the psychological and social lives of Asian Americans. Family influence, especially parental, has been known to predict career choices in math and science-related fields for Asian Americans. This family influence can also be associated with conflict such as the stress of dealing with high expectations of parents to do well. This possibility suggests that families need to be involved in career counseling efforts with Asian Americans.

#### **Occupational Stereotyping**

Historically, Asian Americans have been victimized by occupational stereotyping as a function of gender and/or race. Usually stereotyping is observed across three domains: (1) probability of success, (2) qualifications of training, and (3) acceptance by others. A study found both positive and negative stereotypes with regard to gender and race groupings. However, the research investigating the specifics and psychological impact of these stereotypes has yet to be empirically studied, especially with regard to internal and external barriers, but these effects still need to be considered in counseling.

#### **Occupational Discrimination**

Asian Americans are known as the model minority group, often associated with success and high aspirations. As a result of this portrayal of being able to overcome injustices and setbacks toward success, Asian Americans are usually not considered to be exposed to stereotypes or discrimination. This usually ends up covering up the occupational constraints, obstacles, and inequalities experienced by Asian Americans. Contrary to popular belief, Asian Americans do experience discrimination (e.g., Asian American males are less likely than Whites to occupy management

positions and are less likely to get equal pay despite having higher competencies), and counselors need to be able to acknowledge those experiences.

#### **Occupational Segregation**

Asian Americans have been subjected to occupational segregation, for they have been observed to be overrepresented in some occupations while underrepresented in others. For instance, Asian Americans demonstrate a pattern of gravitating toward the biological and physical sciences, while avoiding the social sciences and humanities. Asian Americans compared to other ethnic groups have also been segregated into lower paying jobs and denied access to higher paying jobs. This segregation arises from societal and cultural barriers imposed on the occupational aspirations of Asian Americans, suggesting that counseling may involve advocacy efforts.

### **Assessment Instruments and Other Factors**

Assessment of career issues is an important precursor to successful career counseling and intervention. This is an important phase to consider as Asian Americans can be perceived to be less mature than Whites as a result of their different decision-making processes, a difference that in turn can lead to biased hypotheses. This assessment phase needs to consider occupational interests, values, choices, and behaviors on the individual level and processes such as segregation, discrimination, stereotyping, and family influences on the social-group level. Due to the lack of sufficient empirically validated career assessment instruments, care needs to be taken to use these measures with a considerable amount of caution.

When counseling Asian Americans, certain factors need to be highlighted. For example, Asian Americans display large within-group variability and differences. Each ethnic subgroup within the larger Asian group has its own culture and history. Other factors include Asian values such as respect for elders and family, issues of loss of face or maintaining face, effects of processes such as acculturation and immigration, gender role differences, expectations and values, and socioeconomic class differences.

## CAREER COUNSELING, GAY AND LESBIAN

---

Gay and lesbian persons refers to men and women, respectively, whose primary sexual attraction is toward people of the same sex. Nonetheless, the word *gay* is sometimes used as a collective term to include both gay men and lesbian women. Due to negative stereotypes, societal stigma, oppression, and discrimination related to homosexuality and nonconformity to traditional gender roles, gay and lesbian persons often face internal and external barriers in their career development and adjustment. Professional literature addressing career counseling issues with gay and lesbian persons began to emerge in the 1980s. Some of the most important topics include career choice, work discrimination, and coping strategies. These topics are introduced below, followed by a discussion of career counseling with gay and lesbian clients.

### Career Choice

Stereotypes and the limited research available suggest that compared with heterosexual persons gay men and lesbians tend to aspire to or be employed in occupations that are nontraditional for their gender (e.g., interior designers, nurses, hairdressers for gay men; landscapers, mechanics, bus drivers for lesbians). A study found that gay men had higher social and artistic interests, but lower realistic and investigative interests when compared with heterosexual men. These findings signify gay men's nontraditional career interest patterns. On the other hand, scientific research on lesbians' career interests and choices is still lacking.

It is not certain from literature whether gay and lesbian persons' nontraditional career interests are intrinsic or a result of attraction toward occupations that are more accepting of gay men and lesbians. In any case, gay and lesbian persons may be affected by society's negative reactions to gender nonconformity and its stereotypical association with homosexuality, resulting in barriers in implementing nontraditional career choices.

### Work Discrimination

Work discrimination based on sexual orientation is legal in the United States, from federal employment to private sectors. One theoretical model identifies three dimensions of work discrimination related to homosexuality. The first dimension includes formal and informal discrimination. Formal discrimination refers to institutional policies or decisions that are unfair to gay and lesbian employees (e.g., a lack of nondiscrimination policy or domestic partner benefits; hiring, firing, salary, promotion, and job assignment decisions). Informal discrimination pertains to interpersonal or workplace climate that is unwelcoming or hostile to gay and lesbian workers (e.g., social isolation, prejudice, harassment, and physical assault). The second dimension includes potential and encountered discrimination. The former refers to possible discrimination should a person's same-sex orientation be known or assumed by others. The latter refers to the encountering of discrimination after the person's same-sex orientation is known or assumed. The third dimension includes real (based on reality) and perceived discrimination (based on the person's perception). These three dimensions result in eight different kinds of work discrimination that may have various effects on

the work status, well-being, and coping of gay and lesbian workers.

### **Coping Strategies**

To deal with the aforementioned forms of work discrimination, gay and lesbian workers may use different coping strategies for survival, self-protection, and self-assertion. A number of coping strategies have been identified in literature, two sets of which are discussed below.

#### ***Identity Management***

To cope with potential discrimination, gay and lesbian workers may use strategies to control the disclosure of information about their gay or lesbian identity, a process called identity management. Five strategies were identified in literature: (a) acting (engaging in heterosexual relationships to make believe that one is heterosexual, e.g., bringing a date of a different sex to a company party), (b) passing (fabricating information to make believe that one is heterosexual, e.g., changing a partner's name and pronoun or making up a story about having a heterosexual relationship), (c) covering (censoring information related to one's homosexuality, e.g., telling a coworker about attending a book club when it is a lesbian book club), (d) implicitly out (allowing interface between work and personal lives without explicitly identifying oneself as gay or lesbian so that people can make their own conclusions, e.g., taking a same-sex partner to a company party without identifying that person as a romantic partner), and (e) explicitly out (explicitly identifying oneself as gay or lesbian, e.g., displaying the picture of a same-sex partner at work and telling coworkers about the partner). These five strategies progress from hiding one's sexual identity to being the most open about it. They may be used sequentially depending on the identity development of the person, or they can be used at about the same time depending on the situation and risk assessed. For example, a person may use the covering strategy in one job interview and the explicitly out strategy in another job interview in the following week.

#### ***Discrimination Management***

When encountering work discrimination, gay and lesbian persons may apply various strategies for the

purpose of discrimination management. Researchers identified three categories of discrimination management strategies: (a) nonassertive (e.g., quitting, silence, avoiding discriminatory persons or situations, using self-talk, or overcompensating in order to evade discrimination), (b) social support (from partner, friends, family, coworkers, and counseling professionals), and (c) confrontation (with offender, complaint to supervisor or human resources, taking legal actions, approaching the media, or circumventing company policies). Multiple strategies may be used simultaneously, depending on the person's sexual identity development, personality, resources available, and the specific situation.

### **Career Counseling**

Career counseling with gay and lesbian clients may involve a number of issues. First, counselors may examine how their own values and beliefs regarding homosexuality or gender-role conformity may influence their work with gay and lesbian clients. Supervision, consultation, continuing education, or referrals may be considered. Second, when conducting career assessments with gay and lesbian clients, counselors examine possible assessment bias and attend to the appropriate use and interpretation of assessment tools with these clients. Third, counselors can explore with gay and lesbian clients how their sexual identity may play a role in their career development. Some clients may feel that their sexual orientation is irrelevant to their careers, whereas others may feel that it is important to be able to express their sexual identity in the workplace or to be able to serve or advocate for the gay and lesbian communities through their careers. Clarification of these values will be important for career planning. Fourth, counselors can assist their gay and lesbian clients to examine how negative stereotypes, oppression, and discrimination may affect their career choices and adjustment. A better understanding and more accurate assessments of the various forms of work discrimination as well as gaining competence with various coping strategies will be helpful. Counselors help their clients identify the most appropriate coping strategies based on their sexual identity attitudes and risk assessment for discrimination and enhance clients' mastery of such strategies through exploration of resources, role-play exercises, and reinforcing clients' self-efficacy. Furthermore, effective counselors refrain from

imposing their values on whether, when, and how clients should come out in the workplace. Instead, they are sensitive to clients' needs, values, and cultural backgrounds in helping clients manage their sexual identity and encountered discrimination. Finally, counselors may engage in social advocacy in order to facilitate changes in the systems that perpetuate oppression and discrimination.

United States in the latter 19th century out of societal upheaval, transition, and change. This new profession was described by historians as a progressive social reform movement aimed at eradicating poverty and substandard living conditions that had been created by the rapid industrialization and consequent migration of people to major urban centers at the turn of the 20th century.

The social upheaval in the United States that gave birth to career counseling was characterized by a host of economic issues: the loss of jobs in the agricultural sector, increasing demands for workers in heavy industry, the loss of permanent jobs on the family farm to new emerging technologies such as tractors, the increasing urbanization of the United States, and the concomitant calls for services to meet this internal migration pattern—all this in order to retool for the new industrial economy. Returning veterans from World War I and those displaced by their return also heightened the need for career counseling.

### First Stage: Job Placement Services (1890–1919)

The focus of the first stage in the history of career counseling was job placement. Frank Parsons, the founder of career counseling, began as a social worker heavily influenced by the work of Jane Addams in Chicago. In Boston, Parsons established a settlement house program for young people either already employed or currently unemployed who had been displaced during this period of rapid change. The placement of these young people into new jobs was one of the initial and most important purposes of this new agency.

Parsons's career counseling model was grounded in simple logic and common sense and relied on the observing and interviewing skills of the counselor. Parsons stated that there are three broad factors in the choice of an occupation: (1) knowledge of self, (2) knowledge of the requirements for success in different occupations, (3) matching these two groups of facts. This largely intuitive and experiential foundation of career counseling formed the basis for Parsons's establishing the Vocation Bureau at Civic Service House in Boston in 1908, the first institutionalization of career counseling in the United States.

During this first stage, an important factor in the establishment of career counseling was the increasing involvement of psychological testing with career counseling. Psychological tests became an important

---

## CAREER COUNSELING, HISTORY OF

---

Career counseling, or vocational guidance as it was originally known, has a long history within the counseling professions. Career counseling was born in the

and necessary part of the first functional stage in career counseling, that is, self-assessment. Testing gave career counseling respectability in U.S. society. Without a scientific procedure to justify this first stage, it is unlikely that career counseling would have been so popularly accepted. Francis Galton, Wilhelm Wundt, James McKean Cattell, and Alfred Binet made important contributions to the newly emerging field of psychological testing and through extension to career counseling.

Another important factor in the establishment of career counseling was the early support for vocational guidance that came from the Progressive social reform movement. Child labor laws were the reason for this collaboration as this crusade to prohibit the exploitation of children grew. Although some states beginning with Pennsylvania had established minimum age laws in the latter half of the 19th century, the first decade of the 20th century continued to see over half of a million children from 10 to 13 years of age employed. Effective federal legislation did not come about until the passage of the 1938 Fair Labor Standards Act. Parsons was a prominent leader in the struggle to eliminate child labor.

Furthermore, laws supportive of vocational guidance were beginning to receive much social support. For example, the landmark Smith-Hughes Act of 1917 established secondary school vocational education training. This legislation was strengthened in succeeding years by the George-Reed Act (1929), George-Ellzey Act (1934), and the George-Deen Act (1936)—all supporting vocational education as an important part of the public schools. Furthermore, in 1913 the U.S. Department of Labor (DOL) was founded, and the Bureau of Labor Statistics (BLS), which had been part of the Department of the Interior, was moved into the DOL.

Also out of this transition came the founding in 1913 of the National Vocational Guidance Association (NVGA; now the National Career Development Association [NCDA]) in Grand Rapids, Michigan, at the Third National Conference on Vocational Guidance. The founders of NVGA included Frank Leavitt (first president), Jesse B. Davis (second president), Meyer Bloomfield (third president and Parsons's successor at the Boston Vocation Bureau and teacher of the first course in vocational guidance in 1911 at Harvard University), and John M. Brewer (fifth NVGA president and author of the definitive history of career guidance in the United States, 1942).

## **Second Stage: Educational Guidance in the Schools (1920–1939)**

Educational counseling, the second stage in the development of career counseling, emerged from the work of humanitarian, progressive social reformers in the schools. Such reformers included Jesse B. Davis, who served as a counselor on educational and career problems at Central High School in Detroit in 1898 and Eli Weaver, who was a New York City school system principal in 1906. Promoting career development in the schools, however, was slow work. For example, as late as the 1930s there were no vocational guidance programs in at least half of the schools in cities in the United States with populations of 10,000 or more. Elementary and secondary education, however, received an influx of students both as a result of increased needs for literacy to cope with increasing demands of industrialization and the increase in numbers of school-aged children as a direct result of the boom in pregnancies following the end of World War I.

Organized labor's strength was growing fast in the wake of the economic depression, and President Franklin Roosevelt's New Deal was a response both to the growing power of unions as well as to loss of jobs. The Civilian Conservation Corps (CCC) was established in 1933 to provide training and employment opportunity for unemployed youth, and the educational services of the CCC were supervised by the U.S. Department of Education.

Then, in 1935, the Works Progress Administration was established through federal legislation as an employment source for the millions of people out of work. Finally, the B'nai B'rith Vocational Service Bureau was opened in 1938 in Washington, D.C., and local Jewish Vocational Services were established in 25 major U.S. cities. The first edition of the *Dictionary of Occupational Titles* (the official government occupational classification) was published in 1939.

## **Third Stage: Colleges and Universities and the Training of Counselors (1940–1959)**

The third stage was characterized by the focus of societal resources on colleges and the training of professional counselors as response to a new social transition engendered by two major events that set the tone for all subsequent worldwide actions: World War II and the USSR's (Union of Soviet Socialist

Republics—now the Commonwealth of Independent States, including Azerbaijan, Armenia, Belarus, Georgia, Kazakhstan, Kyrgyzstan, Moldova, Russia, Tajikistan, Turkmenistan, Uzbekistan, and Ukraine) successful launching of rockets that orbited Earth and even landed on the moon.

First, World War II focused the energy and attention of all nations of the world on this contest between nationalistic fascism (Germany, Japan, Italy) and capitalism–communism, which were allied at this time (United States, USSR, Great Britain, France). President Harry S. Truman's Fair Deal program was a response to the problems encountered by returning armed services veterans. The lack of jobs and the subsequent displacement of current workers by these returning veterans were important societal problems that the Truman program attempted to address.

Second, the USSR successfully launched the first space probe (*Sputnik I*, 1957), followed by *Lunik II* (1959) landing on the moon. These two events more than any other humbled American capitalism for a time. The United States had considered itself far superior technologically to any other country on Earth; however, when the USSR was so successful in their space program, this impelled federal legislators to begin to address the problems in science and math education all across the United States. The passage of the National Defense Education Act (NDEA, 1957) was a direct response to this. The Counseling and Guidance Training Institutes were established under NDEA to provide training for counselors who were to identify and encourage science and math majors for college education. This was a boom period for the training of counselors and almost 14,000 counselors received training in these NDEA Institutes.

Two social conditions characterized the post–World War II period that led to the rise of the professional practice of career counseling: (1) the personal and career problems of veterans, especially those who were disabled during the war; (2) the influx of new types of students to higher education (generally older, nontraditional) as a result of the GI Bill of Rights.

As a direct result of the growth of vocational guidance and the realization that there was strength in joining together with other professional organizations, the NVGA became one of the founding divisions of the American Personnel and Guidance Association (later to become the American Association for Counseling and Development, and now the American Counseling Association) in 1951.

### **Fourth Stage: Meaningful Work and Organizational Career Development (1960–1979)**

The 1960s were a time of idealism and hope. John F. Kennedy's election as U.S. president (1960), Lyndon Johnson's Great Society (1965), the beginning of the great modern-day civil rights movements, the Vietnam War, and the economic highs of this stage all came together to focus a generation of young people on the potential, myths, and illusions of American society, providing for them a new vision of personal, social, and cultural relations.

Many young people wanted jobs that were meaningful and that would allow them to change the world for the better. Young Americans were questioning the character of available jobs and the overly conforming and depersonalizing conditions under which most individuals worked. The United States at that time was regarded as a rich, sophisticated, yet humane nation dedicated to providing all of its citizens with a broad spectrum of services and opportunities for achieving the good life. And young people wanted the United States to live up to its ideals.

The type of federal legislation enacted into law during this period is also illustrative of the expectations of Americans during this fourth stage. At the beginning of the 1960s, the unemployment rate was 8.1%, the highest since the 1930s. President Kennedy entered office in 1961 and as one of his first acts appointed a panel of consultants on vocational education who issued their report through the U.S. Department of Health, Education, and Welfare in 1962, which stated that school counselors need to also have exceptional understanding of the world of work and its complexities. Their recommendations were written into legislation in the Vocational Education Act of 1963 and updated through its amendments in 1968 and 1976.

This report was soon followed by more federal legislation similarly crafted. Not since the founding of the United States in 1776 had there been such a plethora of social programs enacted into law in such a short time, including the Area Redevelopment Act (1961), Manpower Development and Training Act (1962), Economic Opportunity Act (1964; this act created Job Corps, Neighborhood Youth Corps, Volunteers in Service to America, Youth Opportunity Centers, and Head Start), Social Security Act (1967; this act included Work Incentive Program for welfare clients).

Finally, the National Occupational Information Coordinating Committee (NOICC) and the State Occupational Information Coordinating Committees were established by the Vocational Education Act Amendments of 1976. These supra- and intragovernmental coordinating agencies were designated to coordinate the delivery of labor market and other career information among four federal agencies—the Employment and Training Agency, National Center for Education Statistics, BLS, and the Education Commission—and among similar state entities. Led by Juliet Lester, this forced yet historic alliance among such federal agencies to make career information available for coordinated public use was to have far-reaching consequences in the next 20 years, for it would supply the information needs for both the career counselors who required such data for their livelihood and the general public who required such data for career decision making.

As a direct result of the legislation enacted during this fourth stage, career counseling in organizational settings came to the forefront of the career counseling movement. Growth in career counseling in governmental agencies, nonprofit community agencies, and business and industry were the hallmarks of this stage. Such governmental agencies as Lawrence Livermore National Laboratories and Office of Management and Budget had large career development centers with substantial staffs. Such companies as Glaxo Pharmaceuticals, Pacific Bell, and IBM also developed internal career services centers.

### **Fifth Stage: Independent Practice Career Counseling and Outplacement Counseling (1980–1989)**

The late 1970s, however, were characterized by a declining economic system rather than by the growth and prosperity of the early 1960s. This began the fifth stage transition in the 1980s—from an industrial age to an information and technology age. This new transition spawned another host of problems, such as loss of jobs in the industrial sectors of our economy, increasing demands from employers for technological skills, loss of permanent jobs to contract labor, loss of job security, and marginalization of organized labor—all in order to retool for the information and technology economy.

In 1987, the Hudson Institute commissioned and published a report titled *Workforce 2000*, which laid

the foundation for the career development policies of both presidents George H. W. Bush's (1988–1991) and Bill Clinton's (1992–2000) federal administrations. This report was particularly noteworthy in the history of career counseling because of its demographic assumptions about the composition of the new American workforce, that new entrants into that workforce will be predominantly ethnic and racial minorities.

During this stage, the emergence of the private practice career counselor was the direct result of the beginnings of national acceptance of career counseling as an important service to provide to a citizenry in occupational transition as well as to the proliferation of mental health private practices. This practitioner whose livelihood depended on continuous marketing of short-term career counseling provided the vitality for the expansion and growth of the professional practice of career counseling during this period as well as for the credentialing of such practitioners.

NVGA had always taken the lead in establishing standards for the profession: (1) standards for the practice of vocational guidance, (2) standards for occupational materials, (3) standards for the training of counselors, and (4) standards for vocational counseling agencies. As a result of the emergence of the private practice career counselor and the heavy pressure from within the profession, NVGA initiated a specific credential for career counseling professionals. The National Certified Career Counselor credential included substantial academic and experiential requirements along with an examination (National Career Counselor Examination). As a precursor to that credential, NVGA promulgated Vocational/Career Counseling Competencies in 1982, which were developed as a list of competencies necessary for counselors to perform the task of career–vocational guidance and counseling. These competencies were preceded by the AVA–NVGA Position Paper on Career Development (1973), the APGA Position Paper on Career Guidance (1975), the ACES Position Paper on Counselor Preparation for Career Development (1976), the AIR Report on Competencies Needed for Planning, Supporting, Implementing, Operating, and Evaluating Career Guidance Programs (1979), and the APGA Career Education Project (1980). NVGA then established the National Council for Credentialing Career Counselors in 1983; and using the above competencies, this independent credentialing body developed the National Career Counselor Examination that was

first administered at the 1984 AACD Convention in Houston, Texas. Also, in 1984, a letter of intent to affiliate was filed with the new National Board for Certified Counselors (NBCC). The National Certified Career Counselor credential became the first specialty certification area for NBCC.

Concurrent with the emergence of the private practice of career counseling, outplacement counseling also had its beginning. *Outplacement* is a term used when a company is having economic difficulties and begins to downsize or fire currently employed workers to decrease staffing costs and increase profit margins. Outplacement counselors are then brought in to help those workers find new employment—placement outside of their company. Outplacement led to the founding of such firms as Bernard Haldane; Drake, Beam, and Morin; Lee Hecht Harrison; and Right Associates, who competed for these lucrative outplacement contracts side by side with career counselors in independent practice.

The rise in the use of technology in business and industry in the United States led to the passage of two very important federal laws during this stage: Omnibus Trade and Competitiveness Act (1988) and Carl D. Perkins Vocational Education Act (1984). The Omnibus Trade Act included provisions to assist persons to enter into or advance in high technology occupations or to meet the technological needs of other industries or businesses as well as preemployment skills training, school-to-work transition programs, and school–business partnerships.

The Carl D. Perkins Vocational Education Act became law in 1984. This replaced the Vocational Education Act of 1963, which had been amended in 1968 and 1976, and extended federal authorization for vocational education programs through 1989. It was notable for strengthening programs for underserved populations, listed as “disadvantaged individuals, handicapped individuals, adults requiring training/retraining, Indians, limited English-proficient students, participants in programs to eliminate sex bias in vocational education, native Hawaiians, single parents/homemakers, criminal offenders, and unemployed or workers threatened by unemployment.” The Perkins Act has been amended continuously by the federal government, but even today continues to be the vehicle for career guidance authorization in the schools.

During this fifth stage, NVGA was in transition as well, and the change of name in 1984 to the NCDA completed a process begun by Donald Super in the

1950s. Super’s developmental theory led to a redefinition of vocational guidance as a more life-span, now termed career, developmental orientation. The acceptance and use of this new concept, career development, by practitioners and theoreticians alike was the necessary precursor to the organizational name change.

### **Sixth Stage: New Directions (1990–Present)**

At the end of the 1980s and beginning of the 1990s, career counseling had found itself being extended in a variety of new directions: upward (outplacement, senior executives, with attorneys), downward (poor people, resume writers for homeless), outward (schools and agencies through federal legislation), and inward (multicultural and other specialties).

The upward extension was into the populations of business executives who had rarely used these services before, but now through economic imperatives (they were losing their jobs and had nowhere else to turn) they found themselves looking for work at times in their lives when they should have been planning for a financially successful retirement from the companies that they had spent their entire lives building.

The downward extension was into the poor and homeless socioeconomic classes who were being required to go to work because of new governmental policies like the Greater Avenues to Independence, the Job Training Partnership Act, Welfare to Work (1997), and Workforce Initiative Act (1998). The Welfare to Work Act (1997) was the harshest of these laws as it set a 5-year limit on any person in the United States receiving economic support through a federally administered economic support program called Temporary Assistance for Needy Families, which replaced the federal program called Aid to Families with Dependent Children. The idea was to get those who have experienced or have characteristics associated with long-term welfare dependence into unsubsidized jobs, to get them in jobs first (called a work first service strategy), and then to train them postemployment. The role of career counseling and development professionals was to assist in this process where they could, a process that varied from state to state and from local agency to local agency.

The outward extension was brought about through renewed interest and support for career development through the policies of the federal government. Not since the 1960s had so many important laws affecting

American citizens' career development been passed. Beginning with President George H. W. Bush and carrying over to President Bill Clinton, there was a resurgence in interest in the lifelong career development of the American populace, as shown in such federal legislation as the School-to-Work Opportunities Act (1994), One-Stop Career Centers Act (1994), and Americans with Disabilities Act (1990), along with the reauthorization of the Carl D. Perkins Vocational and Applied Technology Education Act Amendments of 1998 (formerly titled the Carl D. Perkins Vocational Education Act), the Higher Education Act, and the Elementary and Secondary Education Act.

The role of organized career counseling and development professionals and federal agencies working together through the NCDA, American Vocational Association (AVA; now Association for Career and Technical Education), NOICC and State OICCs, and American School Counselor Association was pivotal to the final legislation authorizing the School-to-Work Opportunities Act. This legislation began a revolution in the process of schooling in the United States by refocusing the nation's educational resources on the very real, difficult, but underattended transition that all students must make from schooling to jobs. Finally, an inward development was that specialties within the field of career counseling began to be developed by career counseling private practitioners. Such specialties included multicultural populations (African Americans, Asian Americans, gays and lesbians, people with disabilities), attorneys, senior executives, and spousal and international relocation to name but a few. Such increasing specialization is the result of the maturing of a profession.

The changing demographics of the American workforce also came to the forefront during this period. Ken Hoyt addressed NCDA in 1988 and reviewed the progress that women and ethnic and racial minorities in the United States have made during the past 20 years. Hoyt, who worked for the U.S. Department of Education and wrote their definition of work, was president of both the American Counseling Association and NCDA. These changing demographics have led to a greater emphasis in career counseling on multicultural counseling skills.

Another aspect of the sixth stage is an increasing technological sophistication that has led to instant communication by telephone, facsimile transmission, and the Internet to anywhere in the world. Personal communication devices such as pagers and cellular-digital

telephones have made it possible to contact people wherever they are. Extensions of these changes for the career counselor was the provision of career services over the Internet and by telephone as well as the opening up of career counseling markets in other countries.

With the dissolution of the former Soviet Union, opening of economic doors in China, and the steady 7% annual economic growth in Southeast Asia, career counselors from the United States have also expanded their practices internationally. This expansion has included substantial energy and economic investment in taking career counseling to other countries. Career counselors from the United States are doing substantial contract work in Singapore, Russia, China, Hong Kong, Malaysia, Australia, Estonia, and Poland, to name but a few. This is only the beginning of this trend as these technological advances drive the worldwide dissemination of information and innovations in the delivery of career counseling services.

## CAREER COUNSELING, IMMIGRANTS

---

For counselors working with immigrants, it is essential to first understand how and why people immigrate to the United States, and what challenges they face once they are here. The Center for Immigration Studies estimates that as of March 2005 there were 32.5 million immigrants in the United States, accounting for about 12% of the population. Furthermore, 7.9 million immigrants arrived here between 2000 and 2005, making this the highest 5-year period for immigration in U.S. history. The majority of current immigration to the United States is from Mexico, though growing numbers of immigrants come from other Latin American countries, as well as from Asia, Canada, and Eastern Europe. The primary reason for immigration to the United States is a perceived opportunity for economic growth beyond what is available in the individual's country of origin. Others come to the United States as refugees as a result of political turmoil or natural disasters in their home countries. In some cases, only one family member will move initially, planning to send money home and to relocate the rest of the family once she or he becomes established.

Processes for immigration vary. Some individuals obtain temporary visas for educational or work purposes and then apply for permanent resident status. For individuals working in high technology fields, employers may assist in this process. Permanent residents hold what are called *green cards*. Others may apply immediately for permanent resident status based on family members in the United States or for humanitarian reasons (refugees, individuals in need of medical treatment, or those seeking political asylum). Since 9/11, this process has become much more difficult, however. Because of substantial backlogs in the processing of immigration paperwork, temporary visas may expire before an application for permanent residency is approved. Then, an individual or family is faced with the difficult choice of giving up an established life or remaining in the country illegally. For families with children who were born here, and thus are U.S. citizens, this decision can be wrenching.

In many cases, the process of legal immigration appears so overwhelming that desperate individuals or families, particularly from very poor countries, attempt to immigrate to the United States without any legal status. This is a dangerous process involving covert border crossings, falsified documents, and exploitation by

individuals who assist in the process but may threaten to expose an immigrant's illegal status if exorbitant demands for payment or services are not met. In the case of female immigrants, these demands may include forced sex. Of those immigrants who arrived between 2000 and 2005, about half either came here illegally or lost their legal status when their visas expired.

### Challenges for Career Counselors

Counselors may encounter immigrants in a variety of settings, including schools, community agencies, and mental health clinics. Immigrant children—including children of illegal or undocumented immigrants—may receive career counseling in a more traditional secondary-school setting. Adults may seek career counselors as part of a job search or as a result of personal counseling that raises career concerns. Counselors who are doing outreach in poorer communities may also work with undocumented immigrants and may be called on to help with the process of obtaining legal status.

As with all career counseling, part of the process is providing information. With immigrants, this is likely to include basic employment concepts in the United States, including taxes and Social Security, pay periods, and benefits. The U.S. Citizenship and Immigration Services Web site ([www.uscis.gov/graphics/index.htm](http://www.uscis.gov/graphics/index.htm)) provides helpful information to guide new immigrants and their counselors through this process. However, there are significant barriers to employment of immigrants. While federal law prohibits discrimination because of immigration status, discrimination nonetheless remains a significant issue. Limited English skills or a strong accent can pose difficulties for obtaining employment, particularly in jobs requiring a great deal of interaction with English-speaking customers, suppliers, or coworkers. Also, interpersonal styles that may be appropriate in the immigrant's country of origin may be considered inappropriate here—and these may be misconstrued as arrogant or aggressive. In such cases, a counselor may be able to assist by role-playing with the client in a mock interview. Even if the above issues are addressed, however, professional credentials from foreign countries are often not recognized in this country. Thus, immigrants who held professional positions in their countries of origin may face significant underemployment, which contributes to increased financial stress as well as to feelings of loss.

In planning a career intervention, approaches to general multicultural counseling are equally important in career counseling. For example, counselors should consider the client's worldview and value orientation, including the degree to which the client's home culture is individualistic or collectivistic. It may be important for those from collectivistic cultures (Asian or Latino/a, for example) to consider the needs and desires of the family rather than solely one's own personal needs and interests in determining a career goal.

Gender issues may be significant in immigrant couples, particularly when the culture in the country of origin was more male dominant. Because of increased opportunities for women in the United States and because women may be more willing to take lower-status positions, the female partner is likely to find employment first. Thus, traditional gender roles may become reversed as the wife provides the primary financial support for the family. If the couple has children, they may also acculturate faster than will their father, increasing strain in the family because of behavior that their father may perceive as disrespectful of his authority. In this case, career counseling for a male immigrant may require also addressing his loss of status, power, and ability to provide for his family—all of which contribute to diminished self-efficacy, family conflict, and potential depression.

The stress of adjusting to a new culture can compound the stresses of unemployment or underemployment, particularly when this culture must be negotiated in an unfamiliar language. Loss of social support networks and extended family contact may contribute to a sense of isolation. Furthermore, traumatic experiences prior to or during immigration can affect clients' overall functioning—which clearly can affect their occupational functioning.

For career counselors working in more traditional high school or college settings, it is likely that counseling will be more related to career choice than immediate employment. Recent research has established the cross-cultural validity of Holland's RIASEC (Realistic, Investigative, Artistic, Social, Enterprising, and Conventional) model of career personality and work environment, and the 1994 and 2004 revisions of the Strong Interest Inventory have also increased its cross-cultural validity. Because children often become quickly acculturated, this work may be closer to traditional career counseling. However, it is important consider the role the family

and their culture may play in these students' educational and career choices.

## Ethical Issues

In doing any type of counseling, the American Counseling Association Code of Ethics mandates that counselors consider the cultural backgrounds of their clients in their assessment, diagnosis, and treatment. Furthermore, counselors and agencies must provide translators if necessary. Note that to avoid conflict in family roles and to demonstrate respect for parents, it is not appropriate for minor children to be used as translators.

Other ethical issues may become more complicated by immigration status, particularly with undocumented immigrants. Particularly after 9/11, immigrants face legal restrictions of the types of employment available to them. While children who were born in the United States are full citizens, those who came as infants with their parents may still lack the necessary documentation and may face legal challenges to higher education and employment following high school. Thus, counselors should assist and advise clients in obtaining necessary credentials as appropriate, but they should avoid encouraging a client to pursue a career path that may not be legally available.

Finally, when counselors become aware of career barriers related to employment discrimination, it may be appropriate to take an advocacy role to assist the client in obtaining legal support. Before doing this, counselors are ethically obliged to consult with their clients to obtain consent to this role.

## CAREER COUNSELING, LATINOS

---

Latinos are a diverse group of individuals with ancestry in Spanish-speaking countries in Central and South America as well in the Caribbean. Currently Latinos are the largest ethnic minority group in the United States; government projections estimate that in 2050 almost 25% of the total U.S. population will be Latinos.

Career counseling with Latinos requires counselors to move from traditional frameworks of career counseling, for there are unique issues that arise from Latinos' experiences that may influence career development. When providing career counseling services to Latinos, counselors must embrace a broader perspective that takes into account personal and social contexts.

Knowledge is a key component to culturally competent practice, and understanding issues that are central to Latinos' career development process can

facilitate effective career counseling. Historical (discriminatory policies), sociological (immigration factors, networks, socioeconomic status), sociocultural (acculturation, ethnic identity), and psychological (self-efficacy) factors may interact to influence the differential social, educational, and occupational experiences of Latinos. Competent career counselors should be informed about the roles these factors play in shaping the career opportunities and decisions of Latinos, while incorporating this information with appropriate theoretical frameworks to develop a plan for effective career counseling.

### Latino Issues in Career Development

Many factors are important to the career development of Latinos; this entry highlights a few salient factors that may either influence or impede Latinos' career development, focusing particularly on the role of culture.

### Career-Related Self-Beliefs

Among the self-beliefs that are important to evaluate in career counseling with Latinos are aspirations, expectations, and self-efficacy or confidence in their abilities. Research indicates that Latinos have high career aspirations, but are less likely to believe that they will achieve these goals. Some have conjectured that the discrepancy between aspirations and expectations may be attributed to the presence of real or perceived career barriers. In addition, a limited exposure to a wide range of activities may restrict their development of career-related self-efficacy beliefs, likely to influence interests and goals in particular career fields. A lack of confidence in abilities can hinder career achievements, for some may aspire to specific career fields but not pursue them due to low self-efficacy beliefs for related activities. Conversely, some Latinos may not even consider certain careers (particularly high-status, high-paying careers in which other Latinos may be underrepresented) simply because they have had limited exposure to learning activities that can give rise to their self-efficacy beliefs in specific career activities.

Career counselors have the opportunity to intervene with Latinos to optimize their career potential. Professionals should assess Latinos' aspirations and goals, as well as explore career expectations to ensure that lowered expectations for success are not inhibiting potential. It is also important to provide access to

information about the world of work, to increase clients' self-awareness of interests, values, and skills, and to help clients identify opportunities for increasing their confidence in their abilities to succeed in the world of work.

### **Family**

Family is a core value for Latinos and thus influences every aspect of their life, including careers. For Latinos, being part of the family unit may be far more important than individual needs (i.e., seeking careers that match personal interests); thus their career decisions may take into consideration how their choices may affect their family. Latinos may also make major life decisions, such as career choices, in consultation with family members and may sacrifice personal needs for the family's welfare. It is important not to judge this Latino cultural value as negative or deviant, but to simply be aware and recognize the role of the family in career decisions. Furthermore, the support of the family for career endeavors and decisions is invaluable and provides encouragement in the face of adversity. Numerous recommendations emphasize the need to incorporate the family, including supporting Latino clients' discussions about careers and career-related decisions and possibly inviting family to counseling sessions.

### **Mentors**

Mentors can be a facilitative factor for Latinos' career development by helping Latinos confront and navigate career-related barriers and by countering negative career-related messages that Latinos receive. Mentors may also be able to provide support and access to information, resources, and networks. Mentors may be able to aid in exploring career options, aid in making progress in career decision making, and affirm career self-efficacy beliefs. Mentors or role models of the same cultural background may be especially important in implicitly conveying the message that, like them, they too can succeed.

### **Environment**

Environment-related factors that influence the career development and opportunities of Latinos include social class and experiences of discrimination and prejudice. In particular, social class influences

career development in myriad ways—from the exposure to career options to the quality of education one receives. Whereas Latinos with more financial privileges are likely to have more flexibility and access to pursue career options, Latinos are highly concentrated in the working class and may not have the financial resources to pursue a wide range of options. In addition, discrimination and prejudice are real factors that influence Latinos' career development, acting as barriers related to race-ethnicity that eliminate the career possibilities.

### **Culture**

The importance of culture cannot be ignored in career counseling Latinos. Culture influences how individuals view themselves and the world around them and also influences how career is constructed and given meaning. Specifically, the influence of self-beliefs, family, mentors, and the environmental context is greatly shaped by acculturation, generation status, cultural values, and racial/ethnic identity. Thus, the individual and additive effects of these variables may vary from one Latino to another; that is, not all Latinos are affected by the same forces or have the same experiences.

## **Career Counseling Theories and Models for Latinos**

In comparison to the past, more research is being conducted on career counseling with diverse populations, but relatively few studies have been conducted with Latino samples. As a result, limited empirical information is available to use for creating new theories to describe Latinos' career development and to develop frameworks for effective career counseling. Consequently, few career theories and models have been developed specifically for Latinos; career counselors often utilize and adapt theories that have been developed to explain the career development of women, persons of color, or individuals in general. When utilizing these theories that were originally designed for the general population and that do not include sociohistorical-contextual considerations or those that have been primarily validated on non-Latino samples, it is important to take into account culturally relevant variables and to understand how culture influences other person-level career factors in conceptualizing and strategizing a plan for career counseling with Latinos.

### ***Latino-Specific Theories***

Rivera and colleagues created a developmental career model for Mexican American women. Central components to this model are values (e.g., family harmony), social issues (e.g., discrimination), and culture (e.g., family) as they relate to the career choice process. Implications for career counseling practice includes structuring interview questions according to the three foundational components to better understand the internal cognitions that may direct Latino clients' decisions. Gomez and colleagues developed another Latino-specific model that depicts the career path as a nonlinear process that is influenced by a series of four interactive concentric life spheres consisting of the self; culture, family, and personal background; context; and sociopolitical conditions. Each sphere consists of various dimensions that help to shape the individual's career development. Thus, a Latina's career development is conceptualized as an interaction of the person's identity, values and life goals, her cultural and gender role socialization, family's aspirations for her, the opportunities, barriers, and resources within her immediate environment, and the historical context in which her life is taking shape.

### ***Multicultural Theories***

Gloria and Rodriguez developed the psychosociocultural model that focuses on individual, environmental-social, and cultural factors simultaneously in counseling Latinos. Specifically, they argue that it is the contextual interaction between these factors that provides more accurate perspectives of Latinos. Using this framework in career counseling would provide culturally relevant career information to Latinos in the world of work. Furthermore, Blustein's psychology of working provides a framework for career counseling with Latinos. In this framework, work perspectives and experiences may vary depending on the individual, while dimensions of race-ethnicity and social class are also included. Implications for career counseling include discussing perceptions and meaning of work, barriers to work, and discrimination at work with Latino clients.

### ***General Theories***

Major theories have been tested, and in some cases altered, for use with Latinos. For example, social cognitive career theory, typology theories, and developmental

theories have demonstrated support for use with Latinos ranging in age from adolescents to adults. Research continues to be conducted to expand and refine the use of these theories and other career models for use with Latinos.

### **Career Assessment With Latinos**

Important contributions to career assessment with Latinos have identified psychometric concerns that career counselors should be aware of when utilizing traditional career assessment instruments, such as language equivalence, conceptual equivalence, and normative reference data.

### **Counseling Considerations**

The multicultural guidelines offer guidance for providing culturally competent career counseling practice. In terms of working with Latinos, career counselors need to recognize personal attitudes and beliefs that may negatively influence their assessment of and work with Latinos. If left unexamined or unchallenged, even well-intentioned attitudes can impede the career counseling process. In addition, career counselors need to understand the Latino client within the cultural context in which her or his life has taken shape. In particular, career counselors must be aware of and sensitive to a family's history of living in the United States and past and current experiences in educational and work systems. Finally, career counselors must utilize intervention strategies that are culturally appropriate and sensitive. Utilizing theories, models, and tools that are sensitive or adaptable for understanding Latinos' career development is important. In summary, assessing personal attitudes, understanding the life experiences of their Latino clients and the factors that combine to shape their career paths, and implementing culturally sensitive intervention practices will ensure the effective delivery of career counseling services with Latinos.

## CAREER COUNSELING, NATIVE AMERICANS

---

The need for effective career counseling and related research among Native Americans is striking. Census data show that Native Americans have the highest

unemployment rates of any minority group with the exception of African American males. Unemployment approaches 50%, and the number of children living below the poverty level exceeds 50% on many reservations. Likewise, American Indians have the lowest rates of persistence in postsecondary education. Despite evidence of academic ability, postsecondary dropout rates are higher for American Indians than for any other minority. American Indians are also underrepresented in graduate programs. Other researchers have found that American Indian students have a lower rate of academic achievement than students in other minority groups. Despite these obvious challenges, relatively little research has focused on Native Americans' career development.

Scholarly writing on career-related issues among Native Americans can be roughly divided into two historic foci. Early research focused primarily on understanding Native Americans' career development vis-à-vis existing theories and used instruments that assumed universal constructs. These efforts could be labeled *modern perspectives on Native Americans' career development*. More recently, career research and practice have used more contextual and culture-driven perspectives. These efforts can be grouped as *postmodern perspectives on Native Americans' career development*. Both of these paradigms have generated findings that have important implications for career counseling with Native Americans.

### Modern Perspectives on Native Americans' Career Development

Early researchers (pre-1990) focused on similarities and differences between the mainstream population's and Native Americans' career development. Some researchers worked to demonstrate the universality of career development constructs by showing similarity between assessment results from mainstream populations and Native American populations. A common assumption in these studies was that the construct being researched (e.g., occupational values, career maturity) and the assessment used to assess the construct (e.g., Kuder, E., Self-Directed Search, Career Maturity Inventory) were valid and appropriate for the Native American participants. Such assumptions were characteristic of the positivistic perspective taken by many researchers and practitioners over much of the last century. Interestingly, the discussion of these studies often included questions about the viability of the constructs and instruments of the dominant culture.

Some researchers took traditional career assessment instruments and proposed the possibility that diverging worldviews of minority groups, including Native Americans, could challenge the validity of their use. Such questions gave rise to the postmodern perspectives that became more common in both research and practice around the turn of the century.

### **Example**

Dennis West conducted a study that related the career maturity of Native American college students to their academic performance. West also compared these correlations to those of non-Native American students on the same variables. The study found that Native American students scored lower on assessments of career maturity and that career maturity ratings were related to academic performance for all students. However, West was confused by the fact that Native American students' career maturity ratings did not seem to increase with age and academic standing as they did with non-Native Americans. He concluded that constructs such as career maturity, at least as they were defined by current research and assessment instruments, may not be appropriate for Native American populations.

## **Postmodern Perspectives on Native Americans' Career Development**

The past 2 decades have seen a marked shift in assumptions about career development among many researchers and practitioners. Frustrated with the positivistic and universalistic assumptions of the modernist paradigm, many have turned to more postmodern perspectives. These alternative perspectives have focused more on the culture, context, and constructions relevant to Native Americans' career development. Rather than take constructs from the existing understanding of career development in the dominant culture and apply them to Native American cultures, these postmodern efforts have worked to understand Native Americans' career experiences from a culturally situated perspective.

### **Examples**

Cindy Juntunen and colleagues conducted a study of American Indian women's perspectives of their career journeys. Responding to questions about the relevance of career constructs based in the dominant

culture, this qualitative study explored the idea of career from the perspective of the participants. The study found that participants had culturally situated definitions of career and that various supportive factors and obstacles impact Native Americans' ability to live in two worlds—the dominant White culture and Native American culture. Biculturality was seen as an inevitable part of a career development, as most workplaces are based in European American values and culture. The use of a qualitative method that reflected the researchers' postmodern leanings led to culturally relevant, context-bound findings. This research also led to recommendations for models and programs of career development that are similarly culturally relevant.

Rod M. McCormick and Norman E. Amundson made a progressive attempt to develop a culturally relevant model of career development for First Nations People (aboriginal peoples in Canada). Their model reflects a postmodern perspective in its attempt to account for cultural values common among First Nations People as well as career development factors common across many cultures.

The growing body of postmodern perspectives on Native Americans' career development includes some culture-specific implications for career counseling and career education. These implications, in addition to some of the implications of modernist perspectives, are outlined below.

## **Implications**

Although many have questioned the validity of mainstream career assessments for Native Americans, evidence suggests that traditional ways of conceptualizing and measuring interests (e.g., Holland's RIASEC—Realistic, Investigative, Artistic, Social, Enterprising, and Conventional—model) are viable with Native American groups. This research suggests that while Native American groups may have idiosyncratic response patterns related to cultural identity, rural locations, or tribal affiliation—the general construct of interests with varying degrees of interrelatedness among them, seems to have utility with Native Americans. This, in turn, suggests that counselors might use Holland code-based assessments with some degree of confidence in both their validity and utility.

Another general implication, supported by both modern and postmodern research, is the importance of considering social connections in career counseling. Native Americans often include tribe, community, or

family in the process of career decision making and career development. This collectivist perspective may also color one's values. For example, a Native American client from a reservation may put a high value on homeland—both the importance of living in a certain physical place and the importance of contributing to one's home community through one's work. Some suggest that career counselors include parents, family members, or tribal leaders in the career counseling process.

Like many people of color, Native Americans often experience the challenge of becoming bicultural as part of their career development. This challenge involves maintaining a commitment and investment in one's traditional culture and at the same time becoming fluent in the dominant culture in order to enhance one's career development. Regardless of one's linguistic background, the process of becoming bicultural can be likened to the cognitive and emotional difficulty involved in learning a new language.

### An Important Caveat

While it is important for counselors to consider how cultural factors might affect Native Americans' career development, it is also important to avoid thinking of Native Americans as a homogenous group. There are more than 500 different tribes in the United States, with more than 250 languages. Canada has 50 First Nations along with other aboriginal groups. Obviously, there is considerable diversity within the broader Native American culture. Career counselors, while considering general aspects of Native American culture, should also attend to specific cultural identity factors such as tribe, community, and language.

Despite these inherent challenges, the recent pluralization of research methods and the breadth of implications they can provide seem to provide a foundation for increasingly more productive research and effective career intervention with Native Americans.

## CAREER COUNSELING IN COLLEGES AND UNIVERSITIES

---

The process of acquiring knowledge is the essence of higher education. Career decision making is a tangible expression of this process, and since almost half of all college students change majors and even more change career goals while in college, career services for higher education students are crucial to the mission of the institution.

### Characteristics of Higher Education Students as Related to Career Decision Making

Developmental theory is the foundation on which career services at colleges and universities are based. Developmental theorists describe students' cognitive maturation as progressing from dualism, where

students view career choice as an irreversible, once in their lifetime decision, to relativism, where students realize that choices are complex and have multiple aspects. Similarly, students' growth can be conceptualized as moving from low commitment to and exploration of options, to having a successfully resolved and integrated ego identity. Career theorists link in to these psychological models by characterizing career development as people progressing through a series of life stages with attending coping behaviors and tasks. Most college and university students find themselves in the exploration stage, a time in which they sort out career choices. Others describe a process of differentiation, where people through life experiences become increasingly aware of their unique types of interests, skills, and values.

In addition to students' broad-spectrum developmental issues described above, university students may have specific concerns related to disability, gender, age, or cultural differences. Through society's prejudicial attitudes and because of their limited life experiences, students with disabilities may make inadequate career choices because they may lack occupational information and/or have an incompletely defined self-concept. Women's career development, research shows, involves attention to personal issues including low self-esteem and self-efficacy, low expectancies for success, math avoidance, and family-career conflict. In addition, gender bias in education and occupations and a lack of role models play a role. People of color may not have the endless opportunities implied by the term *career choice*. Overt and covert racism and a negative self-image may limit their number and kind of career decision-making choices. Finally, adults returning to college to seek retraining or more advanced training may experience stress related to transitions and unmet expectations.

### Types of Services Offered

Career services at colleges and universities tap into students' differential levels of maturation and special needs by providing career decision-making support ranging from individual and group counseling for self-exploration and exploration of the world of work to resume writing and learning job interviewing skills. The services are guided by theory and typically consist of three focal points: knowledge of self, knowledge of the world of work, and ways to match these personal traits with job characteristics. For those in the early stages of development or for those who have

special needs, the model's first focal point may be of most relevance.

To learn more about oneself, individual career counseling is available, an option that may help students examine how the environment and their reactions to its expectations have created their belief systems and notions about career decision making. This kind of career counseling, which most typically happens at university counseling centers, encourages students to examine the role work plays in their life, to problem solve, and to develop a clear picture of their values, skills, interests, and goals. Furthermore, students' interests, values, and skills can be explored using formal and informal assessment devices such as interest inventories, values checklists, card sorts, and computerized career guidance systems. Individual counseling as well as interpretation of assessment profiles likely shape students' academic pursuits, which in turn help students further test and refine their career decision making.

Many of these activities can take place not only during individual counseling, but also as part of group counseling, projects in classes, seminars, workshops, or career clubs provided by the campus counseling center or career center. Class or group assignments address personal interests, skills, and values as well as the content of academic majors and careers. Counselors help integrate the results of such exploration into students' future life-work relationships by problem-solving and decision-making practices.

For those who need less direction, counseling and career centers provide self-directed career planning activities, including computer-guided self-assessments. Through their sophisticated interactive nature, these programs help individuals assess abilities, interests, and values and match these with occupational and educational information.

For those who have decided or tentatively decided on a major, the second element of the paradigm, knowledge of the world of work, becomes the center of attention in career counseling, students are given the opportunity to participate in career events or discipline-related panels and fairs organized by campus career centers, where they can connect with alumni or employers to get information on particular jobs. They engage in informational interviewing to learn about work in a particular field and to start networking. They utilize library and Internet resources for information and may participate in internship and externship programs where they observe and work with professionals. Such activities help students gain

experience, build career-related skills, build mentoring and networking relationships, and further test their commitment to a career choice. Especially students with unique needs because of limited work experience or exposure to the world of work benefit from intern- and externships since they are key to testing and perhaps revising assumptions and self-image. Through these activities, knowledge of self becomes interwoven with the world of work, which represents the third focal point of the aforementioned paradigm.

Finally, career services most typically utilized by students who are ready to graduate involve using resource rooms in the career center, which provide information on careers and job options. Students can explore alumni and parents' career databases as well as job listings in different fields. Web links provide information on job market conditions, future trends, and earning potential in different types of work. Graduating seniors receive help with job search strategies including researching potential employers, writing a resume and cover letter and then learning how to publish them online, and learning how to interview for a job and how to apply for a job online.

### Professionals Providing Career Services

Career services are provided in different offices by a range of professionals on campus. Career decision-making concerns representing identity development or cognitive and environmental obstacles require a broad based kind of counseling often provided by counselors who work in campus counseling centers. These counselors are trained to address immediate and life-threatening crises, but also difficulties with disabilities, relationships, depression, substance abuse, and identity processes, some or all of which could be related to career decision making.

Campus career centers typically provide job placement services, consisting of appraising and dispensing credentials and organizing job fairs, panels, and interviews, but they also offer self-assessment, diagnostic tests and aids, programs and resources on choice of major and career, and counseling in career exploration and decision making.

Cooperative education and internship programs include myriad experiences consisting of out-of-class, during-the-school-year, summer work, for-credit, not-for-credit, salaried, and volunteer activities. They may be housed in academic departments, in career centers or placement offices, or in a specifically designated office.

Advice on the selection of appropriate course work, helping students recognize the complexity of professional schools' admission processes, writing letters of recommendation, and helping students gain information on admission into professional schools is offered by administrators, faculty advisors, and mentors in academic departments such as prelaw, dentistry, or medicine.

Minority student services offices were created to recruit those that historically had been unable to attend college, and they provide services to help people of color in the areas of residential, academic, financial, and personal concerns. As it became clear that career horizons of women and people of color needed to be expanded, career advising and programming have been added to minority service functions.

Finally, academic departments and colleges, alumni offices, the office of financial aid, student employment, adult and women's resource centers, and campus libraries are involved in career services.

Career services at colleges and universities are important to traditional and nontraditional students; to their parents, faculty members, and administrators; and to the campus as a whole since they help directly and indirectly advance higher education's mission of teaching, research, and public service.

## CAREER COUNSELING IN ORGANIZATIONS

---

Career counseling in today's work organizations reflects career development's dynamic history in North American business and industry during the 20th century. A 21st-century perspective on this counseling specialty encompasses the practitioners, the places, and the procedures of career counseling in organizations.

### 20th-Century Foundation

#### *Industrial Era*

The dawn of 20th-century North America witnessed a continued decline in the agricultural-based economy as the Industrial Revolution advanced. The burgeoning economy, with its need for selection and assignment of personnel to an ever-expanding array of jobs, promulgated the first vocational programs. With the influx of immigrants and veterans into the labor force following World War I and World War II, corporate giants such as Ford Motor Company, R. H. Macy and Company, and Western Electric's Hawthorne Plant initiated industrial-based programs with a mental health emphasis. Psychiatrists, personnel or industrial psychologists, as well as social workers commonly staffed the vocational programs of this era.

#### *Information-Service Era*

Toward the middle of the 20th century, the industrial era peaked as an information-based and then a service-based economy emerged by the final quarter-century. Unprecedented geopolitical, socioeconomic, and biotechnical advances culminated in the restructuring of the North American corporate landscape (e.g., divestitures, mergers-acquisitions, downsizing, and outsourcing jobs offshore).

The postindustrial economy brought with it an increased focus on workers' mental health. Corresponding to growth in individual psychology, there was added appreciation for the role of individual career choice in contrast to employer selection of individuals. Consequently, to the litany of career service providers, were added occupational psychiatrists, vocational-career psychologists, and employment-career counselors.

### *Organizational Settings*

The career specialties were not the exclusive domain of business and industry. A number of governmental entities shared the mission of counseling for career development, or *career management*—the preferred term of reference outside of the educational arena. These included military bases, with an emphasis on the translation of military to civilian occupations, as well as rehabilitation settings, which focused on the employment needs of persons with physical and/or mental disabilities. Correctional facilities and the U.S. Employment Service carried the charge of facilitation of skill acquisition, as well as securing continuous employment.

Beyond corporate and governmental agencies, there were civic or public settings where career counseling occurred. Prevalent among these were mental health and/or substance abuse centers. These settings targeted mediation of the effects of psychological and substance abuse issues on employability.

### Contemporary Perspective

#### *Professional Identity*

Providers of career counseling in organizations are divisible into two general categories: professional counselors and nonprofessional counselors. Professional counselors, those possessing counseling and/or counseling-related graduate degrees, licenses, and certifications, most often have as their primary professional identity, counselor or psychologist. As such, their main professional affiliations are the American Counseling Association (ACA) and the American Psychological Association (APA). Career, as a professional specialty, may be indicated by membership in ACA and APA divisions promoting careerism:

National Career Development Association and National Employment Counseling Association, both divisions within the ACA, and the Society for Vocational Psychologists, Division 17 (Counseling Psychology) of the APA

Career practitioners who deliver counseling and/or counseling-related activities but who are not professional counselors/psychologists may carry the following titles: career development facilitator, career adviser-specialist, career management consultant (outplacement), employment-workforce development specialist, job-search trainer, job developer, and career

coach. Those paraprofessional counselors frequently hold membership in the following professional affiliations: Association of Career Professionals International, Society of Human Resources Managers, American Society of Trainers and Developers, Career Planning and Adult Development Network.

## Role and Function

### *Organizational Perspective*

Career practitioners provide counseling services via internal and external relationships with organizations. Career professionals who are employees are often a part of the human resource function. Practitioners external to organizations, by contrast, provide services on a contingency or contractual basis. Both internal and external career professionals perform a variety of roles: from the organizational to the individual level. At the system or organizational level, career professionals target the organizational structure by programmatic design, implementation, and staffing and evaluation of career services.

In general, the role and function of career practitioners varies by the organization's location on the business life cycle. For example, an employing organization at the start-up phase requires a wide range of highly skilled workers, those who will immediately drive production and create a market presence. Then, as the organization moves to the establishment phase, there is a corresponding need for consistency of production or service delivery, to demonstrate the organization's earned place among its competitors.

As the organization reaches the advancement phase of the business life cycle, the need shifts toward more innovation and distinctive products or services—that which differentiates the organization from its competitors and defines its market niche. As each phase requires unique general characteristics from its workers, so change the role and function of the career practitioner in helping identify and develop the workforce.

## Career Counseling Interventions

The counseling methods used to effect career enrichment, advancement, and transition vary across the historical eras. During the industrial era's vocational guidance movement, intervention strategies-of-choice were individual interviewing, history taking, and test

administration and interpretation. These methodologies were particularly driven by an explosion in psychometric testing and individual counseling techniques advanced by the then leading theories of counseling (e.g., behavioral, developmental, and existential).

The information-service era added computer-assisted career guidance systems as a convenient intervention for the administration of assessment tools and the delivery of occupational, educational, and company information. A second strategy of this era was the accelerated use of group guidance (e.g., information, general direction) and counseling (e.g., self-knowledge and self-change) as cost-effective interventions for the greatest number of workers in an organization. In addition, this period saw assessment centers and corporate universities, with their emphasis on self-assessment, self-guided learning, and skill training, reach a zenith.

## Future Prospects

Historically, the ebb and flow of societal change directly influenced the nature of work in organizations. Consequently, as the workplace evolves, there is a need for ongoing application of emerging counseling strategies and techniques to the confluence of organizational and individual needs. The contemporary workplace suggests the following as the individual and organizational issues for career counseling's future:

- the influence of work-life issues on career decision making and adjustment;
- the public health movement will embrace career fitness (e.g., career adaptability, career resilience);
- the positive and negative impact of corporations without walls on workers' well-being;
- redefinition of career—individual adopts multiple work roles/styles (e.g., free agent, contingency worker, employee, and entrepreneur) across the life span;
- the application of cybercounseling techniques to the stages of career development (i.e., entry and establishment, maintenance, and advancement and the transition and disengagement);
- movement beyond focus on recruitment and retention to psychological engagement as the litmus test of stellar performers;

- transformation of organizational cultures to one that is values-driven and developmental (e.g., emotionally, spiritually, and culturally); and
- increased demand for retirement counseling that integrated the role of leisurite with meaningful work during late-adulthood (age 65 and older).

Whatever the structure of work organizations in the future, whether physical or virtual, career counseling is positioned as an intervention-of-choice for individuals and groups of individuals confronted by the challenge for effective entrance into, adjustment within, and separation from work organizations.

## CAREER COUNSELING IN SCHOOLS

Career counseling in schools exists at the intersection of the career education program and the provision of personal counseling. It potentially draws from and contributes to both individual pupils' career development and individual counseling. Career counseling has been a core activity of the school counseling movement from the time of Frank Parsons, and although its nature has changed in response to theoretical and societal developments, it remains a central part of the work of the counselor. This aspect of the counselor's work enables contributions to be made to young people's future planning and may provide evidence of a more visible role that school counselors can play.

### Defining Characteristics

Career counseling in schools needs to be differentiated from the broader category of school-based career interventions due to its more personalized nature characterized by career-focused face-to-face interaction and focused on occupational selection and decision making in relation to the individual's view of self in relation to life and future work roles. In contrast to other forms of counseling, the use of some form of assessment may contribute to the discussion and planning process. While career education promotes career development through its focus on knowledge and skills, career counseling enables the individual to refine the process through consultation and discussion. In the literature, there has been an extensive debate about interaction between personal counseling and career counseling with many authors acknowledging not only their complementarity, but also the distinctive sets of specialized skills needed by counselors in both aspects of the work.

### Impact of Developmental Stages

Career education begins (whether explicitly a part of the curriculum or not) in elementary school, but career counseling is more likely at particular phases of secondary school. Career choices are among the most important decisions any young person has to make. Young people today have greater awareness of the world of work as they experience the impact of parents'

occupations, with more mothers working, and may see friends and older siblings struggling to find employment or experiencing work as stressful. They also develop ideas about the working world through television viewing. In adolescence, the learner is developing a sense of personal identity and refining ideas about the self.

Career counselors are likely to see youth at various stages of the career development process with varying levels of readiness for planning and decision making being evident through the course of adolescence, and differences across a cohort will be evident at key decision points. Some studies have shown that as young people approach school-leaving, it may be the parents rather than the individual who show more concern or express anxieties about the future.

In adolescence, individuals are located within the exploration stage (as first identified by Donald Super), and young people will have developed different levels of competencies in the different tasks required to progress in this stage (self- and occupational awareness, crystallization, and specification). James Marcia expanded on Erik Erikson's work related to adolescent identity development and identified four identity statuses: foreclosure (where the young person tends to conform to expectations), diffusion (where the young person has not yet committed to a direction), moratorium (where active exploration of alternatives is occurring), and achievement (good progress has been made toward a sense of identity). It is very important for career counselors to be sensitive to these variables because they have a substantial impact on the young person's readiness for engagement in the process and because different individuals will have different needs at any point. Some measures of career maturity or readiness for career decision making have been developed; for example, the Career Decision Scale (developed by Super and his colleagues) and the Career Maturity Inventory (see Crites, John O.).

Through the provision of career education, young people should be exploring four aspects of the career choice process:

- self-awareness of capacities, interests, and skills and social–personal development;
- knowledge of the diversity of careers and developing the skills of accessing information of relevance;
- building awareness of the opportunities open to them; and
- decision-making skills.

The role of career counseling is to personalize this process for the individual, especially at key decision-making points, such as when selecting subjects and courses of study and especially as the person approaches school-leaving and the related transition period.

## Information and Its Application

Since the time of Parsons, the occupational world has grown tremendously both in size and complexity. This growth has made the skills of accessing and understanding career information an essential aspect of career counseling. The complexity of accessing up-to-date career information is challenging because there is only one constant—that of ongoing change. It is therefore necessary for providers of career information to use systems that are capable of being expanded and are sufficiently flexible to provide adequate assistance to support the counseling process.

## Contextual Considerations

The rapidly changing world of work at the beginning of the 21st century poses great challenges for school-based career counselors. Accelerating technological change, the influence of globalization, and the impact of economic events have resulted in people needing to adapt to changes in the world of work in unprecedented ways. Careers are evolving, moving away from job stability and security in the hierarchies of government and big corporations of the industrial era toward the following:

- labor-intensive, low-tech, and competitive informal groupings where people are expected to multitask and where there is little security;
- flatter hierarchies, teamwork, and contract work characterized by job mobility;
- entrepreneurial careers not dependent on structures, but dependent on individual skills, adaptability, and the willingness to take risks; and
- the use of agencies to provide services and the employment of part-time and piecework workers requiring greater individual flexibility.

The new career realities are therefore unpredictable, uncertainty, and insecurity with the likelihood that individuals will move away from initial choices. The skills of adaptation, lifelong learning,

compromise, and adjustment will all be required; potentially increasing levels of stress for many may be sources of marginalization and exclusion for those who are ill prepared. This change requires the counselor to be sensitive to both contextual and personal variables and risks when jointly exploring possibilities with young people.

### **Counselor Knowledge, Roles, and Competencies**

The school counselor will require knowledge and competencies in generic counseling skills-process and specific career-related aspects, which may be more directed and information driven. It is important to make links to other forms of individual counseling in order to assess where the two might intersect and inform the other, as well as seeking links to the counselor's preferred theoretical orientation to promote active listening and problem solving within the chosen framework. Alternatives to individual face-to-face counseling may also need to be sought, for example, e-mail communication, and there is great potential for small group counseling sessions to optimize available time. Further considerations relate to parental engagement and involvement (in contrast to some other aspects of personal counseling). There is great value in utilizing forms of career assessment to promote self-understanding and assess progress in terms of career development, but it is important that the chosen instruments are as free of gender and cultural bias as possible.

The roles of the counselor may therefore expand on those of traditional counseling, including information provision, group assessment (to then feed into individual understandings), consultation (e.g., in career education program development and related to pupils' developmental processes), and facilitation of linkages, in particular those related to school-to-work schemes. It is also important for the counselor to be sensitive to issues related to disability (of various kinds) and diversity (such as race and minority group).

The National Career Development Association (NCDA) of the United States has developed a list of competencies in 11 designated areas: career development theory, individual and group counseling skills, individual/group assessment, information/resources, program management and implementation, consultation, diverse populations, supervision, ethical/legal issues, research/evaluation, and technology. To explore

these areas, descriptions of these competencies may be accessed from the NCDA Web site.

### **Theoretical Developments**

Traditionally, trait-factor approaches, material related to John Holland's theory and Super's models, have formed the basis of career counseling. These approaches have been complimented by psychological inventories that have aided the process of information gathering and counseling. Career information processing has gained ground in the past decade and has acknowledged the importance of thinking and decision-making skills as well as higher-order metacognitive contributions to career development and adaptation. Each of the aforementioned theories and approaches to counseling emphasizes the individual as a processor of information and has been critiqued for making assumptions about the self (as something relatively fixed and self-contained) and the relationship between the individual and the environment that may not be appropriate in non-Western contexts.

Alternative ways of approaching career counseling include constructivist and hermeneutic approaches and the use of a developmental-contextual framework (such as that developed by Fred Vondracek and colleagues). Such approaches are focused on gaining a shared understanding of the perspective of the young person and the many influences (social, cultural, educational, historical, and political) to which he or she has been exposed. Reality is viewed as a collective construction through language and social discourse, leading to the individual incorporating many perspectives. These are subject to negotiation and reinvention over time as the person takes on different roles and responsibilities, depending on changes in the situation. These approaches employ more qualitative data gathering techniques; an example is *My System of Career Influences* developed by Mary McMahon and associates.

Middle-class counselors need to be particularly sensitive to the limitations on choices and challenges experienced by learners from disadvantaged backgrounds. It is important to constantly consider the need to be inclusive in order to reach out to minority groups and to be more responsive to learners' contexts.

Time constraints often affect school counselors' capacities to offer comprehensive career counseling. While it is ideal to be able to spend a number of

sessions with one individual, to cover the complexities of the personal and situational variables in a developmental way, this may be limited to briefer interactions and sessions. It is thus necessary to work in close collaboration with broader career education programs in order to optimize available time. The competent counselor has an important role to play in the school's efforts to promote the career development of youth and to prepare young people for the challenges they face.

## CAREER COUNSELING PROCESS

---

Career counseling has been defined as an ongoing, face-to-face interaction between counselor and client with career- or work-related issues as the primary focus. The goal of career counseling is typically to assist individuals in developing self-understanding, articulating direction in their careers, and achieving their potential and discovering their purpose in daily activities.

There are indications that many people at some point during their lives would like assistance with career planning or with making decisions related to vocational or occupational issues. Although there are some uncertainties related to what specific process factors should be included in career counseling, there are still indications that most clients benefit from participating in career counseling. It should be noted that there are many similarities between the process of career counseling and personal counseling, but counselors need specific training for career counseling. More knowledge is needed, however, on the underlying processes and mechanisms that lead to effective change in career counseling. Specifically, there is a need for additional research related to which career interventions work with whom and under what conditions.

Multiple studies have found that individuals benefit from career counseling, and this entry will discuss the research related to the process of the career counseling that assists clients with work issues. More specifically, career counseling process relates to the overt and covert thoughts, feelings, and behaviors of both clients and counselors while engaged in career counseling. This discussion of the career counseling process will address the following: (a) whether career counseling process is different and distinct from personal counseling, (b) process factors that positively affect outcome, (c) process factors that negatively affect outcome, and (d) process factors worthy of additional investigation.

### Process in Career Counseling Versus Personal Counseling

There has been a long and extensive debate about the distinctions between career counseling and personal counseling or psychotherapy. Some scholars have argued that there is research support for the integration of career and personal counseling because there are similarities among clients, associated with research related to similarities of clients; common elements or counseling techniques; and similar outcomes for many clients. Both career and personal counseling clients share common problems, and they are not different in terms of level of adjustment or amount of emotional discomfort. In career and personal counseling, counselors use many of the same helping skills. A study conducted in England found that clients, counselors, and expert witnesses all agreed that the career guidance interviews were more effective if the counselor helped the client feel comfortable in

discussing personal information. Interestingly, both career and personal counseling have been found to decrease clients' harmful psychological symptoms and to increase their abilities to solve problems. Although the process of career counseling is similar to personal counseling, practitioners also need to know about career or vocational theories and specific interventions strategies.

### **Process Factors That Produce Positive Outcomes**

In comparison to psychotherapy research, there is limited process research in career counseling and therefore significantly less is known about the relationship between the process of the counseling and what contributes to positive results. However, researchers have identified five critical ingredients that should be included in any type of career counseling. The five critical ingredients are written exercises, individualized interpretations, occupational information, modeling, and attention to building support. Each of these critical ingredients contributes to positive outcomes for clients, and research suggests that clients benefit from the addition of each critical ingredient to the career counseling process.

Other researchers have found outcome in career counseling to be positively influenced when the counselor encourages clients to engage in self-exploration and provides emotional support. Other process factors found to be helpful in career counseling were helping clients clarify assets and values, providing feedback from tests, and incorporating occupational information.

### **Process Factors That Negatively Influence Outcome**

In addition to factors that positively influence career counseling process, there is knowledge related to factors that have little effect or that negatively influence outcome. It is important that career counseling involve a counselor, as there is substantial research that indicates that counselor-free interventions (e.g., Internet assessments) are not effective. In addition, there are indications that individuals do not consider the following to be helpful: (a) tests that do not produce new leads, (b) exercises that do not yield sufficient career direction, (c) unskilled counselors (e.g., inattentive, mechanical test interpretation), and (d) insufficient assistance in finding adequate career information. Counselors need to be trained on how to conduct

career counseling in order not to use ineffective activities. Ineffective career counseling activities, such as ones that are poorly selected or are implemented in a haphazard manner, are not helpful to individuals who need help with their career planning.

### **Process Factors Worthy of Additional Investigation**

Although there is an expanding body of research that can guide counseling psychologists about the most effective processes in career counseling, there are still areas where additional research is needed to provide more detailed clinical guidance to practitioners. One of the areas of substantial research in personal counseling or psychotherapy concerns the importance of the working alliance. The alliance is often conceptualized as (a) counselor and client agreement on the goals of therapy, (b) counselor and client agreement on the tasks to achieve the goals, and (c) the quality of the emotional bond between counselor and client. Experts in the field of career counseling frequently indicate that they work on establishing a therapeutic relationship when describing their approaches to career counseling; however, some researchers have not found a significant relationship between the working alliance and the positive outcome.

There are also some questions about the most effective number of sessions in career counseling, which is often referred to as the *dose effect*. Some researchers have found that longer career counseling tends to produce better results for clients. Other researchers have found that the most effective career counseling occurs in four or five sessions.

Another area in which counselors need to conduct more research is related to what types of career counseling work best for which types of clients. Even though there has been research that documents the vocational obstacles and barriers often faced by minority clients, there has been very little exploration of whether differing types of career interventions are more productive with clients from different racial and ethnic backgrounds. There are some models that have been developed to provide career counseling specifically for clients from diverse ethnic and racial backgrounds, but there has yet to be sufficient investigations of whether these models improve career outcomes for these clients.

Another area of fertile research related to the process of career counseling concerns effective methods for conducting and interpreting career assessments.

This is surprising given the significant role assessments have traditionally played in career counseling. In addition, many of the research studies related to the process of career counseling have been with college students, and additional studies are needed with older adults who are experiencing a variety of career transitions. For most people, work has a daily impact on their quality of life; therefore, it seems important to identify career counseling process factors that can assist individuals in finding work that is both satisfying and rewarding.

## CAREER DECISION-MAKING DIFFICULTIES QUESTIONNAIRE

---

Dealing with career indecision has long been a focus of theory and research, and helping clients to overcome their difficulties in making decisions is among the core roles of career counseling. The Career

Decision-Making Difficulties Questionnaire (CDDQ) is based on the taxonomy of career decision-making difficulties proposed by Gati, Krausz, and Osipow and was developed to validate the proposed taxonomy and to be a means for locating the focuses of individuals' career decision-making difficulties, a step that is among the first in providing individuals with the help they need.

### The Taxonomy of Career Decision-Making Difficulties

This taxonomy provides a decision-theory-based systematic framework for characterizing an individual's career decision-making difficulties. It comprises three major categories of difficulties, which are further divided into 10 specific difficulty categories. Lack of Readiness includes three categories that precede the actual engagement in making a specific career decision: *lack of motivation* to engage in the career decision-making process, *general indecisiveness* concerning all types of decisions, and *dysfunctional beliefs* about career decision making. The other two major categories focus on difficulties that may arise during the engagement in the process. Lack of Information includes *lack of knowledge about the steps involved in the process* of making a career decision, *lack of information about the self*, *lack of information about the various occupations*, and *lack of information about the ways of obtaining additional information*. Inconsistent Information includes three categories of difficulties in using the information: *unreliable information*, *internal conflict* within the individual (such as contradictory preferences), and *external conflicts*, involving disagreements with significant others.

### The Revised CDDQ

The revised version of the CDDQ consists of 34 items (with a 9-point response scale), including 2 validity items and 2 to 5 items per scale. The individual's difficulties are summarized in a 10-scale score profile corresponding to the 10 difficulty categories, each representing the mean of the responses to the items included in it. The empirical structure of the 10 categories was found similar to the theoretical one. The reported test-retest reliabilities range from .67 to .80, the median Cronbach-alpha internal-consistency

coefficients of the 10 scale scores range from .68 to .84, and that of the total CDDQ from .87 to .96. After the credibility of the responses to the questionnaire and the differentiation of the 10 scale scores are ascertained, the core of the interpretation involves locating the focuses of the individual's difficulties on the basis of the relative salience of the scale scores; reservations are added when needed. The CDDQ allows a multidimensional assessment of the individuals' difficulties. Further information on the CDDQ, including its Internet version with validated interpretation and an abridged professional manual with the studies that tested or used it, can be found at [www.cddq.org](http://www.cddq.org).

### Research Findings

The construct and concurrent validity of the CDDQ was supported by analyses of both the paper and pencil and the Internet versions of the questionnaire with various cross-cultural samples. Specifically, its pattern of correlations with various other measures, including the Career Decision-Making Self-Efficacy Scale, the Career Decision Scale, the Vocational Decision-Style Indicator, and the Career Thoughts Inventory, were as expected. A large difference in the total CDDQ score was found between decided and undecided individuals. Finally, the focuses of clients' career decision-making difficulties as located by the CDDQ were found compatible with the conclusions of career counselors. The CDDQ was found useful in face-to-face counseling for the initial assessment of individuals' career decision-making difficulties and as a measure of the effectiveness of individual and group career-counseling interventions.

## CAREER DECISION SCALE

---

The Career Decision Scale (CDS) grew out of S. H. Osipow, C. Carney, J. Winer, B. Yanico, and M. Koschier's counseling experience with undergraduate students who sought help in dealing with their inability to decide on an educational or career goal. Specifically, it was thought that identifying a limited number of problems connected with that indecision would lend itself to the development of specific counseling interventions designed for helping resolve career indecision.

Based on clinical experience, a limited number of statements were devised, each designed to allow the client the opportunity to indicate the degree to which each statement describes his or her situation. Ultimately, 16 indecision type statements were devised along with 2 statements of a decided type for a total of 18 items. The respondent is required to indicate on a 4-point scale the degree to which each statement accurately described his or her situation. From these responses, a total undecided score can be calculated by summing the one to four responses for each of the 16 undecided items as well as a total certainty score by adding the two decided items. Thus, scoring is simple, and a total indecision score can be generated for each respondent.

A variety of reliability and validity studies have been conducted on the instrument. These include studies of the correlation of the CDS with other instruments purporting to measure career indecision. The studies also assessed the ability of the instrument to differentiate between self-proclaimed decided and undecided students as well as students of different levels of career maturity. In all, the results of these studies generally support the validity of the CDS.

Studies of the effects treatment for indecision were also made in a variety of settings, again generally indicating that the instrument is responsive to interventions for career indecision. Test–retest reliability measures have generally shown high correlations between undecided scores over short time periods, but not so high that interventions would be unable to change an individual's status.

Finally, a number of investigators have studied the factor structure of the measure. Here, the results are mixed with some studies finding four factors, others fewer, and the interpretation of each factor being slightly different. The factors have been described as a lack of structure and confidence in dealing with vocational decision making, an external barrier to a preferred choice, an approach–approach problem where two options appear to be equally attractive, and finally a personal conflict of some type interfering with implementing a choice.

The interpretation of scores is based on a set of norms—norms for high school males and females, college student males and females, adults seeking continuing education, and adult women returning to college—and on comparisons between males and females at the high school and college levels. Comparisons by age are also available.

In summary, the CDS can be useful in counseling by identifying problem areas. It can also be useful in measuring the outcomes of various group and individual interventions to deal with career indecision and has the virtue of well-established norms, reliability, and validity.

## CAREER DECISION SELF-EFFICACY SCALE

---

The Career Decision Self-Efficacy Scale (CDSE) was developed by Karen Taylor and Nancy Betz in order to apply Albert Bandura's theory of self-efficacy expectations to the domain of career decision making. Career decision self-efficacy was originally defined by Taylor and Betz as the individual's belief that he or she can successfully complete tasks necessary in making career decisions. In order to define these tasks, the theory of career maturity of John O. Crites was used. Crites's theory defined career maturity as the individual's degree of possession of five career choice competencies and five career choice attitudes. The five career choice competencies and sample items are (1) accurate self-appraisal ("Accurately assess your abilities"), (2) occupational information ("Find out the employment trends for an occupation over the next 10 years"), (3) goal selection ("Select one occupation from a list of occupations you are considering"), (4) planning ("Make a plan of your goals for the next 5 years"), and (5) problem solving ("Change occupations if you are not satisfied with the one you entered"). In the original CDSE, each scale consisted of 10 tasks in which the individual indicated his or her degree of confidence in his or her ability to complete the task; the response continuum ranged from 0 (*not at all confident*) to 9 (*very confident*).

In 1996 a 25-item short form was developed from the best items of the original 50-item form. The short form has been found to have levels of reliability and validity comparable to or superior to those of the long form. In addition, research by Betz, Marie Hammond, and Karen Multon indicated that a five-level response continuum provided measurement as reliable and valid as that provided with the 10-level response continuum, so it is recommended that most users use the short form with the five-level response continuum.

Based on extensive research evidence, it can be said with considerable certainty that career decision making self-efficacy is related to other indices of adaptive career decision making. For example, there is ample evidence that career decision self-efficacy is inversely related to career indecision and fear of career commitment and that it is positively related to high versus low vocational identity, to more adaptive career beliefs, and to career exploratory behavior. It

has been found that career decision making self-efficacy was related to academic persistence versus dropout in underprepared college students and that it surpassed all other variables as a predictor of academic and social integration of college students.

### Use in Evaluating Career Development Interventions

Research suggests that career decision self-efficacy is strongly related to both perceived and actual difficulties in making and implementing career decision. There has now been considerable research using self-efficacy theory as the basis for the design and/or evaluation of interventions to increase career decision self-efficacy. Many studies have used the CDSE as the dependent variable in evaluating career interventions such as the use of DISCOVER, a computer-assisted career guidance program, and other career counseling workshops and career exploration courses in college student populations. Results consistently indicate that the CDSE scores of students who receive a viable intervention tend to increase, whereas CDSE scores of students who do not receive an appropriate intervention remain relatively stable over time.

## CAREER DEVELOPMENT INVENTORY

---

The Career Development Inventory (CDI) is a 120-item standardized measure of career development attitudes and knowledge first published in 1979. This measure operationally defines career maturity based on Donald Super's theory of career development. In general, the CDI assesses level of readiness for making realistic educational and career-related decisions. There are two forms of the CDI, one for middle school and high school students and another for college students.

Having its roots in the Career Pattern Study, the CDI emerged as the culmination of years investigating central dimensions related to Super's model of vocational maturity. The five basic scales of the CDI are described as follows:

1. Career Planning (CP; 20 items) assesses future orientation and the extent to which one has thoughtfully engaged in educational and career planning activities.
2. Career Exploration (CE; 20 items) measures clients' willingness to use various educational and career resources (e.g., books, counselors) and the efficacy of those utilized.
3. Decision Making (DM; 20 items) measures understanding of the process of effective career decision making based on respondents' solutions to hypothetical career decisions.
4. World-of-Work Information (WW; 20 items) assesses general knowledge of occupations and understanding of how to attain and succeed in certain fields.
5. Knowledge of Preferred Occupation (PO; 40 items) first involves selecting one of 20 occupational groups (e.g., writing and law) to designate one's work interests. Next, the respondent's degree of knowledge regarding typical duties and personal characteristics of workers involved in that particular occupational group is examined.

Consistent with Super's theory, the CDI includes two broad factors—each comprising two cognitive (DM and WW) and two attitudinal components (CP and CE)—in addition to the PO, a separate content domain suitable only after 10th grade. Composite scores are also provided by combining CP and CE to form the Career Development Attitudes (CDA) scale, DM and WW to form the Career Development Knowledge and Skills (CDK) scale, and CDA plus CDK for a Career Orientation Total.

The CDI has multiple uses including career research, practice, education, and program evaluation. Numerous publications provide insights into interpreting results. Beyond the assessment of interests, abilities, personality, and work values, the CDI provides supplementary information on the process of coping with complex tasks associated with choosing a career.

A substantial amount of research has been conducted on the CDI. The content and theoretical relationships between its scales have proven sound. Scores on attitudinal components increase throughout high school. Interestingly, the cognitive scales of the CDI have shown positive relationships to grade point average and measures of intelligence. These associations are slight, but consistently emerge across studies. Although the CP, CE, and WW scales demonstrate sufficient reliability estimates, lower values for DM and PO warrant caution. In addition to these concerns, factor analyses suggest that users emphasize the broader composite scales. Moreover, ongoing needs for investigating its predictive validity persist.

The CDI is an exemplar applied career assessment based on career development theory. Continued efforts to update the measure are necessary to solidify its legacy for informing our understanding of career development.

## CAREER DEVELOPMENT QUARTERLY

---

*Career Development Quarterly (CDQ)* is the premier English-language journal in career counseling and development and is the official journal of the National Career Development Association (NCDA). It was first published in 1911.

*CDQ* publishes articles on career counseling, individual and organizational career development, work and leisure, career education, career coaching, and career management. Each article includes implications for practice as *CDQ* is especially focused on fostering career development through the design and use of career interventions. The methodologies that are used in *CDQ* articles include, but are not limited to, literature reviews that make research accessible to practitioners, case studies, history and public policy analyses, qualitative research, and quantitative research that is of specific relevance to the practice of career development.

*CDQ* is consistently rated highly among all of the applied psychology journals based on the *Social Sciences Citation Index* issued each year, published by the Institute of Scientific Information, and reported in its publication, *Journal Citation Reports*. It tracks the number of times original scientific articles are cited in other journals as a reflection of the impact each article (and collectively, each journal) has on the body of scientific literature during that year. Thus, the more times an article is cited from a journal the more stature it and the journal have as a meaningful contributor to the scientific literature. That impact rating, reflecting the level of academic excellence of the journal, is then used to rank all the journals in the applied psychology field that includes *CDQ*.

Since 1988, *CDQ* has published a comprehensive annual review of the professional literature in career counseling and development titled "Practice and Research in Career Counseling and Development." These reviews are developed and written by accomplished professionals who synthesize the professional literature

for that year around the theme, What can the practitioner learn from this year's literature? These annual reviews are the most requested online articles of all the articles published in *CDQ*.

The *CDQ* Editorial Board comprises senior career counseling and development professionals who are selected to a 2-year term with a maximum of three consecutive terms. The *CDQ* editor recommends individuals for appointment with the election by the NCDA Board of Directors. Reviewers are expected to complete at least one review per month. The *Publication Manual of the American Psychological Association* (current edition) serves as the style manual for *CDQ*.

*CDQ* has evolved from its original 1911 format and has had name changes that were appropriate to its evolution. *CDQ* was published as the *Vocational Guidance Newsletter* (1911–1914, Frederick J. Allen, editor), *Vocational Guidance Bulletin* (1915–1918), *The National Vocational Guidance Association Bulletin* (1921–1924), *The Vocational Guidance Magazine, Organ of the National Vocational Guidance Association* (1924–1933), *Occupations: The Vocational Guidance Magazine* (the official origin of the NVGA; 1933–1944), *Occupations: The Vocational Guidance Journal* (1944–1952), *The Vocational Guidance Quarterly* (1952–1986), and the *Career Development Quarterly* (1986–present).

Recently, technology has had an effect upon how *CDQ* is published and accessed by readers. *CDQ* continues to be published in a print format, but in 2000, *CDQ* articles were first allowed to be accessed online, although full-text articles were only available one year after publication. In 2005, that restriction was removed and all articles were available for immediate electronic access upon publication. Also in 2005, *CDQ* moved to a completely electronic manuscript submission and review process.

Further information on *CDQ* including information for authors is available at the NCDA's Web site.

## CAREER EDUCATION

The use of the term *career education* varies across both time and context. In its broadest sense the term refers to educational activities in formal and tertiary education contexts, which aim to foster and enhance learners' knowledge, skills, attitudes, and values related to occupations and the concept of career development over the life span. In the United States, the term has tended to be superseded by curricular school-to-work programs, whereas in the United Kingdom, the term *career support* is often used for career-related activities facilitated by educators. In countries with outcomes-based approaches to education, career education may be incorporated into life skills-based syllabi rather than viewed as a separate strand in the curriculum. Where learner centeredness underpins educational practice, developmentally and contextually sensitive approaches to career education may be promoted.

Programs may be provided by mainstream educators or led by institutionally based careers advisors, or they may be provided by external agencies contracted for the task (depending on the resources available). Where educators have little specialized training in career theory or practice, consultants may be required to design programs and train practitioners. In some contexts, career education practice may be viewed as ancillary to mainstream education, but agencies providing it may be overstretched and subject to financial constraints. An increasing number of theorists have called for holistically planned programs that are integrated into the curriculum.

Key considerations in the provision of career education, including school-to-work programs, are explicit planning, a focus on the learner's life stage, the concept of work to be employed, an approach that is sensitive and responsive to the local context, and the development of transferable skills that support lifelong learning. These considerations are rooted in both developmental and situational perspectives and focus on the many competences and attitudes that support decision making and transitions into and between work roles. Although in the second half of the 20th century career education may have been predominantly didactic in nature, recent shifts have emphasized learners' constructions and narrative accounts of their experiences.

The rapidly changing world of work at the beginning of the 21st century poses challenges for providers of career education. Accelerating technological

change and the influence of global economic forces have resulted in people needing to respond to changes in the world of work in unprecedented ways. The stability and predictability of industrial era career paths no longer exist, and people are expected to be much more adaptable and flexible. New forms of careers need to be considered, including the increasing independence from organizational structures.

The foundations of career knowledge and the skills of planning and decision making should be laid in schools. Educators need to have a greater awareness of their role in preparing learners for the working world. Thus, classroom activities that make links with work, workplace visits, and different types of work experience are being integrated into the mainstream. There are also increasing calls for career education to be provided to adults in the context of lifelong learning and continuing education.

Career education is particularly relevant in the exploration stage of an individual's career development. This occurs initially in adolescence, but may continue during the process of engagement in the world of work as a young adult. It may also occur when voluntarily changing jobs or career direction or when the individual is forced into exploration owing to retrenchment or the need for retraining.

Four major aspects of careers education have been identified:

1. developing self-awareness through understanding individual attributes, interests, dispositions, ideals, and values that impact on career aspirations;
2. fostering knowledge about opportunities available to learners through information gathering on the spectrum of potential occupations, about the impacts of different types of work on lifestyle, and about ways to access information;
3. building explicit awareness of styles of and skills related to decision making; and
4. coping skills for life-span transitions (e.g., school to work, work to unemployment, into continued education, changes in the workplace, reentry into the job market).

Curricular aspects of career education include a body of knowledge that needs to be accessed, skills that can be practiced, and a philosophy and values that warrant attention and discussion. Career education should also be integrated into adult education and

extended to the work of labor and trade union organizations, as well as to the fields of training and personnel development.

Career education is concerned with preparing the person for the choices and transitions that life presents. One of the major challenges faced by providers of career education relates to the readiness for and motivation of learners. Concepts such as career maturity and career decision making have relevance, and it is important for the provider to investigate the degree of fit between envisaged activities and the individuals for whom these are designed. Career education must be planned to enable learners to develop skills to cope with the information overload, uncertainty, confusion, and challenges to the individual's sense of identity that may characterize experiences of postindustrial life.

## CAREER EXPLORATION

---

Exploration has been a focus of vocational development research since the inception of the field. The concept was originally invoked to explain the process by which a person examines opportunities and

constraints in the labor market in order to choose a job or career. The conceptual definition has been significantly expanded to become an ongoing complex developmental process that is a central mechanism propelling the transition from school to work and career pathways.

### **Brief History of the Exploration Concept**

Donald Super cast the career exploration concept into life-span terms and identified adolescence as the period when a person begins to employ a dynamic form of exploration that involves aspects of the vocational self (e.g., emerging awareness of career interests, values, and related abilities) that guide a person's exploration of the world of work and aspects of the outer world (e.g., feedback on school and work performance) that guide self-exploration. Central to the issue of children's vocational development, Super and others suggested that most preadolescent children were preoccupied with career fantasies because they were incapable of career exploration that involves the integration of psychological, physical, and social structures into an understanding of how a person fits within the working world.

In an effort to expand a life-span theory of career development focused on adolescents and adulthood, Super employed the curiosity and exploratory behavior research on humans and animals to arrive at a developmental model with childhood curiosity being identified as the fundamental antecedent characteristic driving early career exploration. While the construct of curiosity has not received much attention in the career literature, career exploration has become a bedrock construct explored within several popular content domains including work values, self-concept, occupational learning, vocational aspirations, interests, and identity.

### **A Conceptual and Propositional Model of Career Exploration**

Career exploration involves the dynamic interplay between self-exploration and exploration of the world of work that yields a relatively stable sense of the occupational self-identity and with it a suitable and satisfying occupational choice. Jean Pierre Jordaan, working with Super during the 1960s and 1970s, defined *vocational exploration* as conscious and unconscious activities conducted with an aim toward learning

about the self and the work context and how the two fit together. John Holland supported the position that occupational exploration is a fundamental aspect of career development and asserted that the development of occupational interests through exploration is a critical aspect of the process of moving from an undifferentiated sense of the world of work and toward an occupational choice. Hanoch Flum and David Blustein later extended the exploration construct to include exploratory competence, which presumably develops from the act of exploration over time and involves the belief that a person can effectively explore his or her environment (i.e., seek and gain information and insight that will be beneficial).

As career researchers and theorists employed the career exploration construct, they grew convinced that it was a critically important aspect of vocational development, but they also became relatively disconnected from the broader literature on human exploration. Super referred to this literature (e.g., D. E. Berlyne's work), but did not discuss it at length in later reviews of the exploration literature. Moreover, this broader exploration literature enjoyed a major resurgence during the 1980s that went relatively unreported in the career literature

### **The Broader Literature on Exploration**

The definition of *exploration* in the human exploration literature is similar to the established definition in the career literature, but the definitions differ in terms of when children develop a capacity for exploration. Hans-Georg Voss and Heidi Keller defined exploration as the coordination of perception, behavior, and elements of the self such as interests and values that are motivated by a desire or need to acquire new knowledge. Distinct from the career literature, they contended that such exploration occurs in concert with play behavior during infancy and late childhood. This definition suggests that children may engage in career exploration involving the coordination of personal values, goals, and interests and vocationally related or relevant experiences and information.

The human exploration literature further distinguished between two interrelated types of exploration. Children presumably employ combinations of *diversive* and *specific* exploration to learn about their environment. *Diversive* exploratory behavior is presumably driven by stimulation and excitement and much less

affected by psychological structures of the self or social forces. The definition of specific exploration is consistent with the definition of human exploration discussed above and is motivated by learning more about a situation or object in reference to the self. A child presumably enters a novel situation in a diverse exploration mode, scanning the situation to assess the lay of the land. Situations may afford more or less opportunity for a child to employ diverse exploration, and a child may be more or less motivated to do so. During a period of diverse exploration, specific features of the situation are defined as being more or less enticing, exciting, threatening, or inviting. Having identified or been confronted with the most salient features of the situation, the child may employ a specific exploration behavioral pattern to elicit more information and/or an affective response from those features that are most salient to the child, and this behavior will influence and be influenced by elements of the self such as interests, values, and goals.

### Integrating the Broader Literature on Exploration With Career Exploration

The vocational exploration of children may be described as diverse in nature. Young children explore the world of work attempting to comprehend its elements in more or less enticing, exciting, or threatening terms. As children begin to develop vocationally related interests and values through sequences of diverse career exploration, particular aspects of the world of work (i.e., occupations) may become the target of specific exploration, which is commonly known as career exploration. This shift from diverse to specific career exploration is supported by research suggesting that children shift from glamorous career aspirations (e.g., movie star and astronaut) to more realistic aspirations during the later grade and middle school years.

The integration of the human and career exploration literatures suggests that the developmental course of career exploration is to begin the process of career exploration employing diverse exploration until attention coalesces around a broad class of exciting or glamorous occupations and a sense of self emerges. This period of diverse exploration eventually gives way to a period of specific exploration spanning the adolescent and young adult years. Career theorists have generally assumed that the shift from diverse to specific career exploration occurs during adolescence, but a growing body of research in the career literature suggests that this transition may begin

during the middle to late childhood period. Future research efforts could be committed to developing measures of diverse and specific career exploration and ascertaining the typical and atypical timing of the exploration transition during the childhood and adolescent periods.

### Conclusion

Career theory characterizes early to middle childhood as the period when children physically and psychologically explore the outer world and organize this information into increasingly complex categories and associations. The late childhood and early adolescent period has been theoretically distinguished from the earlier periods within the career literature by the use of a dynamic form of exploration that involves a transaction between aspects of a person's inner and outer world in the pursuit of career goals of varying degrees of specificity. The broader literature on human exploration suggests that exploration as a complex interplay between the inner and outer world occurs during the childhood period, and this may have significant implications for future career research. Regardless of the timing of the process, the developmental course of diverse and specific career exploration is predicted to yield a set of career pathways that are consistent with a child's emerging interests, needs, aspirations, and values on the one hand and his or her environmental opportunities and social pressures (e.g., parental wishes and expectations) on the other. Career exploration is, therefore, a critical aspect of child and adolescent career exploration, and parents, counselors, and educators should aim to promote this process in adolescents and at least consider efforts to do so during the grade school years.

## CAREER FACTORS INVENTORY

---

Career indecision has been an important area of concern in vocational psychology for the last 50 years. An extensive body of research has examined the nature of career indecision, the factors (sometimes labeled barriers) that contribute to career indecision, the consequences of career indecision, and the effectiveness of interventions for career indecision. Most of this research has focused on college students. This work has led to and been enhanced by the development of instruments that measure aspects of career indecision.

The Career Factors Inventory (CFI) is a 21-item instrument developed by Judy M. Chartrand, Steven B. Robbins, and Weston H. Morrill to measure four factors that contribute to career indecision. The CFI yields scores on two cognitive factors (i.e., Need for Career Information and Need for Self-Knowledge) and two emotional factors (i.e., Career Choice Anxiety and Generalized Indecisiveness). The first three scales assess the respondent's present status (i.e., state) on factors that are theoretically amenable to change. The Generalized Indecisiveness scale assesses the respondent's status on a trait that theoretically is more resistant to change. These scores are grouped into two categories labeled informational needs and decision needs. The authors recommend the inventory for use in helping clients determine their readiness to engage in the career decision-making process. Career-related

problems outside of this narrow focus are not addressed by the CFI.

### Description

Respondents rate the CFI items using a 5-point scale. Ten of the items use a Likert scale with response alternatives anchored by 1 (*strongly disagree*) and 5 (*strongly agree*). These items begin with the stem, "Before choosing or entering a particular career area, I need to." Each item concludes with a statement identifying a specific task (e.g., "Talk to people in one or more various occupations" and "Attempt to answer, 'Who am I?'" ). High scores on these items indicate greater levels of career indecision.

The remaining 11 items use the semantic differential format. These items consist of a phrase followed by polar opposite adjectives that anchor the rating scale as illustrated in the following example:

When I think about actually deciding for sure what I want my career to be, I feel:

Cold      1      2      3      4      5      Hot

The other two phrases used in the CFI are, "For me, decision making seems," and "While making most decisions, I am." These phrases are followed by six, three, and two polar adjectives, respectively.

The number of items composing each CFI scale and the range of possible scores on the scales are Need for Career Information and Career Choice Anxiety (6 items each; range = 6–30), Generalized Indecisiveness (5 items; range = 5–25), and Need for Self-Knowledge (4 items; range = 4–20).

### Administration

The CFI was designed to be self-administering, self-scoring and self-interpreting; professional supervision of the administration and scoring should be unnecessary. Despite this, the authors advise psychologists to help examinees understand the purpose of the inventory and the four constructs it measures. Competent practice requires that psychologists make sure clients understand their purpose in completing a psychometric instrument. However, explaining the meaning of the scales prior to completing the instrument may influence the results.

The CFI directions are simple, and the inventory has an eighth-grade reading level. It can be administered

to an individual or a group, and it is appropriate for persons ages 13 and older. The CFI is not timed, but most examinees should be able to complete it in 5–10 minutes.

## Interpretation

The Need for Career Information scale measures clients' needs to acquire occupational information and gain experience prior to making a career commitment. The Need for Self-knowledge scale measures clients' needs for increased self-understanding. The Career Choice Anxiety scale measures clients' anxiety about the career decision-making process. The General Indecisiveness scale measures clients' perceived inability to make decisions even though the conditions necessary for decision making have been satisfied. The authors claim that discussion of these scores in counseling can help clients understand the barriers that are hindering their career decision making and lead to the identification of effective ways to overcome these barriers.

The CFI assumes a normal distribution of scores and provides arbitrary statistical cutoffs for interpreting scores on these scales. The authors do not provide a theoretical or empirical justification for this approach nor any empirical evidence documenting the validity of interpretations based on these cutoffs. These cutoffs are based on norms composed of convenience samples of college students enrolled in psychology classes at two universities. Consequently, interpretation of CFI results for clients other than university students is not warranted, and interpretation of university students' results is speculative because of the inadequate norms.

The authors recommend plotting the four scale scores and joining them to obtain a profile, but they do not provide a rationale or empirical justification for this procedure. The order of the scales on the profile is arbitrary, so the shape of the profile lacks rational or empirical meaning. However, the authors do provide case studies that counseling psychologists can consult for guidance.

The wording of the 10 CFI Likert items poses another problem in interpreting the CFI. These items begin, "Before choosing or entering a particular career area, I need to." The authors interpret these items as measuring the respondent's perceived deficit. An equally viable interpretation is that these items assess the respondent's belief that these statements describe a reasonable, commonsense approach to career decision making. Consider the item, "Before

choosing or entering a particular career area, I need to use my free time or school courses to help determine what type of career I might enjoy and do well in." Clients who have already done this might answer, *strongly agree*, to indicate their belief that the statement describes a reasonable approach to career decision making. Consequently, it is likely that some responses to the CFI indicate a perceived need, while others indicate an evaluation of the action described. This item wording may muddy the interpretation of CFI scores and reduce the validity of the instrument.

## Reliability

Test–retest reliability indicates the stability of a test score across a specific time period (2 weeks in the case of the CFI). The test–retest reliabilities of the CFI range from .76 (Need for Self-Knowledge) to .94 (Generalized Indecision). Scores on the CFI scales that measure states are less stable than desirable, given the short time period. Scores on the trait scale are more stable, as is expected. These values indicate that recent CFI results can be interpreted with caution.

Internal consistency reliability indicates the extent to which the items on a scale provide consistent information. Values lower than .75 indicate that the scale items are somewhat inconsistent. Values above .90 suggest that the scale measures a narrow construct that is unlikely to have practical utility or that the scale uses more items than is necessary to achieve adequate precision.

Internal consistency reliability coefficients for the CFI have been reported for samples of middle school and high school students, community college students, 4-year college and university students, adults, and female offenders. The internal consistency reliabilities have ranged from .73 to .91 for the four subscales and from .73 to .92 for the total inventory. The Need for Career Information scale has the lowest reliability, and some internal consistency reliability coefficients reported for that scale have fallen below the acceptable range. The reliability coefficients reported for the other scales have all been in the acceptable range. The General Indecisiveness scale has the highest reliability.

## Validity

### Factorial Validity

Several studies have investigated the factor structure of the CFI, using both principal components

analysis and confirmatory factor analysis. While the results generally support the four-factor structure of the CFI, high correlations have been observed between the Need for Career Information and Need for Self-Knowledge scales ( $r = .80$ ) and the Career Choice Anxiety and Generalized Indecisiveness scales ( $r = .69$ ). This pattern supports the authors' claim that the CFI measures cognitive and emotional factors. Greater measurement efficiency could be obtained by combining the CFI items into two scales, but some information would be lost. The relative advantages of a four-scale and two-scale interpretation of the CFI are not known.

### **Convergent and Discriminant Validity**

Convergent validity is indicated when scores on a scale correlate highly with other measures of the same construct. Discriminant validity refers to the principle that scores on a scale should not correlate appreciably with measures of different constructs. Evidence indicating the CFI's convergent and discriminant validity is provided by correlations with measures of career crystallization, career decidedness, career development, career indecision, career specialization, goal instability, self-esteem, trait anxiety, and vocational identity. However, most of the expected correlations are in the low .30s, several are below .30, and some are even in the opposite direction from that which is expected. Overall, the evidence provides weak to modest support for the convergent and discriminant validity of the CFI.

### **Criterion-Related Validity**

There is virtually no evidence documenting the criterion-related validity of the CFI. One noteworthy attempt compared CFI scores prior to and following a counseling intervention. The change in scores was consistent with the interpretation that the intervention was effective, but two design flaws weaken the credibility of this interpretation. No evidence was presented to document the effectiveness of the intervention, and no tests of statistical significance were reported. Therefore, it is possible that the observed changes were not significant.

### **Evaluation**

The CFI is a simple 21-item instrument that can be used to assess a client's readiness to engage in the

career decision-making process. It assesses four of the many factors that are known to affect career decision making. Career-related problems outside of this narrow focus are not addressed by the CFI.

The stability of scores on the CFI is less than desirable, and its scales possess borderline to modest internal consistency. The factorial validity of the CFI has been supported by several studies, but the pattern of overlapping scales suggests that it primarily measures cognitive and emotional barriers to career decision making. The convergent and discriminant validity of the CFI are weak to moderate, and it lacks meaningful criterion-related validity.

The ambiguous wording of the CFI Likert items creates interpretive problems and it may, in part, account for the weak validity. The lack of adequate norms and the use of arbitrary statistical cutoffs for interpreting scores further exacerbate the interpretive problems. Interpretation of CFI results for anyone other than a university student is not warranted, and interpretation of university students' results is speculative at best.

Finally, the accuracy of self-scoring instruments is always a concern. Mistakes sometimes happen when clients score their own test results. Steps to minimize these mistakes and to document their frequency are essential. The rationale for self-scoring is not obvious given that the CFI has such a narrow range of application.

## CAREER INDECISION

---

Career indecision is the inability to specify an educational or occupational choice and can include focal problems, such as lack of information, or a combination of problems, such as choice anxiety and trait indecision. Career indecision is experienced by high school and college populations not only in the United States, but also in countries such as Belgium, Canada, Portugal, Israel, and Taiwan. Career indecision is a relatively common experience for adolescents and young adults in industrialized countries who are making the transition from formal secondary schooling to higher education or full-time employment. Counselors have an array of assessment tools at their disposal to distinguish between the two major presenting problems: developmental indecision and chronic indecisiveness. Distinct treatment approaches should be implemented for these two forms of indecision.

### The Domain of Career Decision Problems

There are five basic career decision problems.

#### ***Lack of Information and Need for Information***

Lack of information has long been considered to be the primary source of indecision. Information deficit accounts for the largest amount of variance in career indecision measures. Individuals can lack information about personal (“What are my strongest interests?”) and career characteristics (“What do software engineers do?”) or about how to engage in the decision-making process. The modal career counseling intervention is designed to increase self- and career-related knowledge and decision-making skills. Recent findings indicate that students may acknowledge a lack of information without feeling a need to gather more information. Clients who do not express a need

for information are unlikely to value interest–personality assessment or career exploration activities.

#### ***Identity Diffusion***

Identity is a core concept in vocational psychology theory and research. Identity diffusion is reflected in the inability to crystallize one’s career-relevant characteristics or to see a way to implement personal preferences in a career; career indecision may reflect delays or problems in identity development. Researchers have found moderate to strong linear relationships between identity diffusion and career indecision. Undecided students may benefit from interventions that enable them to explore and crystallize their identities prior to extensive involvement in information-gathering activities. Although identity diffusion is highly correlated with perceived lack of information, information gathering may exacerbate confusion for clients with identity diffusion. Both lack of information and identity diffusion can be seen as predecision problems occurring prior to formal decision making.

#### ***Trait Indecision***

Trait indecision reflects chronic and pervasive difficulty in making decisions. Trait indecision interferes with decision making in several domains: relationships, politics, leisure and recreation, spirituality, and career. Trait indecision can interfere with the ability to process and act on information attained through career assessment and counseling. Counselors often recognize trait indecision when they have completed a full course of career assessment and counseling and find that their client (a) has not identified an academic or career goal even when the objective data support one or more viable choices, (b) does not feel ready to terminate counseling, and (c) expresses doubt about her or his decision-making abilities and/or the counselor’s abilities. Trait indecision does not yield to rational analysis or counselor encouragement or support.

#### ***Choice Anxiety***

Choice anxiety is the affective dimension of career indecision. Specifically, it is negative affect experienced in relation to the career choice process and outcome. Choice anxiety can interfere with the client’s ability to gather relevant information, identify salient choice aspects, compare aspects of various choices

under consideration, and determine appropriate choices. Both trait indecision and choice anxiety inhibit the career decision process.

### ***Disagreement With Others***

The final career decision problem relates to disagreement with or disapproval of one's career choices by valued others such as a parent or spouse. This is a decision implementation problem rather than a decision problem because those who anticipate disagreement with others already have successfully formed a career goal. Disagreement with others also is weakly correlated with overall indices of career indecision.

## **Indecision Types**

Conceptualization of career indecision has advanced from a simple dichotomous classification of decided-undecided to multiple-type classification based on cluster analyses of career and personality variables. There is now consensus that there are two distinct career indecision types with differential counseling interventions appropriate for each. Those with developmental indecision have a focal need to acquire career information and initiate career planning. They experience little career choice anxiety, are goal directed, and have ego identity maturity appropriate to their chronological age. Clients with developmental indecision need brief, information-based career counseling.

The second type is chronic indecisiveness, which is associated with need for career information, high levels of negative affect including career choice anxiety, pessimistic views regarding future careers, low decision-making confidence and self-esteem, and poorly developed ego and vocational identity. This type exhibits the identity diffusion, trait indecision, and choice anxiety problems identified in the previous section. As the label indicates, this form of indecision persists over time. For example, it has been demonstrated that career indecision did not decline over a 3-year period for a sample of chronically indecisive French Canadian college students. These individuals require far more from career counseling than to acquire self and career knowledge.

## **Career Indecision Assessment**

Counselors have several tools at their disposal to assess indecision. The Career Decision Scale (CDS)

has been used widely as a global indecision measure. The CDS is unique in being the best available measure of the identity problems that can impede career exploration and decision making. The CDS is somewhat limited in that it does not reflect the full range of career decision problems and there is relatively little information available to assist the counselor in interpreting results. The Career Factors Inventory (CFI) is a brief instrument that reflects the negative cognitive and affective experiences inhibiting decision making. Although CFI does not measure identity diffusion, it provides the broadest coverage of the domain of career decision problems. The CFI is easy to administer and provides good interpretive information for the counselor. The Career Decision-Making Difficulties Questionnaire (CDDQ) is an excellent measure of lack of information and disagreement with others. Because it is not a commercial instrument, relatively little information is available to guide the counselor in interpreting the CDDQ. However, the CDDQ has been translated into several languages, and researchers are actively developing cross-cultural norms for this measure. Finally, the Career Thoughts Inventory (CTI) provides measures of trait indecision, choice anxiety, and disagreement with others. It does not reflect the information deficit or identity diffusion dimensions of indecision. The CTI has an excellent companion workbook that counselors and clients can use to refute negative cognitions associated with trait indecision and anxiety and develop more adaptive thoughts.

## **Career Indecision Interventions**

There are a number of good options for meeting the information needs of students and clients with developmental indecision. First, providing information about personal interests, abilities, and values has been the traditional focus of career counselors. Second, a wealth of career information is available on Internet sources such as the Occupational Informational Network (O\*NET) and America's Career InfoNet. Third, computerized career guidance programs such as DISCOVER are available as stand-alone media or as adjuncts to counseling. Finally, the innovative Making Better Career Decisions system uses a sequential elimination search process to guide users through the career evaluation and decision-making process.

There are three essential elements to intervention for the chronically indecisive. First, counselors must address the pessimistic and negative thoughts associated with trait indecision. It is important to instill hope

that the client can negotiate the challenging decision-making process and that a suitable academic or career goal can be identified. The CTI companion workbook is an excellent resource for developing more adaptive career thoughts. Second, counselors have to stabilize the negative affect associated with chronic indecision. Anxiety can interfere with the process of personal and career exploration and undermine the evaluation of alternatives. Counselors can employ a variety of anxiety management techniques to stabilize mood and clear a working space for career counseling. The third and most challenging goal is working with clients to form a more cohesive identity. Hamachek's articulation of counseling goals based on Erikson's psychosocial framework is a rich resource for counseling to promote ego identity development. Counselors can work with clients to (a) develop autonomy, which increases decision-making self-efficacy; (b) increase initiative by encouraging clients to experiment with novel work, leisure, and relationship roles; and (c) further develop industry. Clients will more readily incorporate personal and career information after developing a more clearly articulated ego identity.

## CAREER INTERVENTIONS

---

Career interventions are activities designed to explore and enhance a person's career development by helping the person make, implement, and benefit from a variety of career decisions. As such, career interventions take several forms. The most common include career counseling, assessment interpretation, group counseling, group assessment interpretation, career workshops, career classes, computer-assisted career guidance systems, and counselor-free interventions.

Career interventions took root at the turn of the 20th century with the vocational guidance movement. Started by Frank Parsons with the establishment of the first Vocation Bureau in Boston, the vocational guidance movement was focused on helping alleviate experiences of poverty and marginalization by providing the knowledge necessary to gain meaningful employment. Parsons theorized that these goals could be accomplished by helping people (a) understand their career interests and personalities, (b) obtain occupational information, and (c) integrate personal and occupational knowledge in a process of "true reasoning" to arrive at a meaningful career decision.

Over time, counselors, psychologists, and theorists have expanded and built upon Parsons's work. The present field of vocational psychology contains career interventions designed to help people not only make career decisions but also find jobs and experience satisfaction in their workplaces.

### Types

#### **Career Counseling**

Career counseling refers to an ongoing set of activities and conversations between a counselor and a client designed to help the client (a) decide which career to pursue, (b) complete a job search, or (c) build a sense of satisfaction and achievement at work. Thus, career counselors work with a wide variety of clients facing different career challenges. The specific form career counseling takes varies depending on the goals established by counselor and client.

Counseling for career choice is focused on helping people decide which career to pursue. Often, clients seeking this type of counseling are either beginning a career or considering a career change. These clients may be undecided for a variety of reasons, including a lack of information, too many or too few attractive options, conflict with others concerning these options, or a general difficulty making decisions. Throughout the course of counseling, clients are encouraged to gain a better understanding of how their personalities, interests, values, and skills might be more congruent with certain types of occupations than with others. Career counselors often ask clients to complete inventories or to discuss their personal backgrounds to help them gain self-understanding. Career counselors then assist clients in gathering information about various occupations. A final step is to analyze this information, generate a set of possible careers, and decide which career to pursue.

Counseling for job finding is focused on helping people implement their career decisions by finding jobs. Clients seeking this type of counseling are often either entering the workforce or looking for new jobs. Over the course of counseling, these clients are encouraged to put effort and intensity into a thorough job search. Job search effort and intensity can be influenced by factors such as personality, self-efficacy, social support, and perceived barriers. Clients who commit a great deal of effort and intensity to the job search tend to meet with success. Career counselors help clients conduct thorough job searches by encouraging effort and assisting with a comprehensive array of resources, including information on job search components such as effective resumes, interviewing skills, and networking.

Counseling for career satisfaction is focused on helping people gain a sense of enjoyment and accomplishment in their jobs. Often, clients who seek this type of counseling are employed, yet dissatisfied with their jobs. Dissatisfied workers are also likely to express difficulty performing job-related tasks, feelings of burnout, and stress. Career counselors help clients explore their feelings of dissatisfaction and consider their options. Some clients might choose to search for new jobs. Others might prefer to redesign their current jobs by developing coping strategies, seeking support, taking on new responsibilities, or building skills to improve performance.

Counseling for career choice, job finding, and job satisfaction are very different activities that share several common characteristics. Career counseling can last from a single session to well over 12 sessions, but

research suggests that 4 to 5 sessions may be optimal for many clients experiencing difficulties in making career choices. Research also suggests that these sessions tend to be most effective when the following components are included: (1) clients record their thoughts, ideas, and goals in a journal; (2) counselors provide individualized feedback and attention; (3) counselors and clients gather information concerning different occupations; (4) clients identify models who are engaged in their careers; and (5) counselors help clients build support networks. In addition, career counselors provide support, challenge career myths, and help clients select and pursue meaningful careers. In a multicultural society, it is increasingly important that career counselors appreciate cultural and contextual factors that may facilitate or limit career options. In order to better counsel an increasingly diverse clientele, career counselors need to increase their understanding of issues such as workplace discrimination, cultural values, racial identity, acculturation, and familial obligations.

### ***Assessment Interpretation***

Assessment interpretation is the process of reviewing, explaining, and discussing the results of an inventory designed to clarify (a) individual variables such as interests, abilities, and vocational needs; (b) process variables such as career maturity; or (c) cognitive variables such as self-efficacy. A clearer understanding of these variables can help individuals gain a sense of self-knowledge, clarify goals, and identify fitting occupations. To this end, assessment interpretation typically occurs in the context of career counseling, although assessment inventories can also be taken and interpreted on computers.

Assessment of individual variables is focused on helping clients develop a clearer understanding of their abilities, skills, interests, values, and personalities. These individual variables are usually measured by having clients complete inventories, tests, or card sorts. One commonly used inventory is the Strong Interest Inventory. This inventory provides a personalized profile of client interests. It also provides a profile indicating how similar a client's interests are to people working in and satisfied with a variety of different occupations. Together counselors and clients discuss these profiles with special attention to how profile themes apply personally and professionally to the client's life. While inventories are commonly used to measure interests and personality variables, card sorts are sometimes used to assess values. In this

process, clients rank order their work values by sorting cards into piles. Once the cards have been sorted, counselors and clients discuss the meaning of each value to the client. In addition to inventories and card sorts, clients might be asked to self-rate their abilities or complete ability tests such as the General Aptitude Test Battery. Tests and self-ratings such as these help clients clarify which abilities they possess.

Assessment of process variables is focused on understanding how people make career decisions. Process variables, such as career decision making, career maturity, and career adjustment, are commonly measured using questionnaires. Together counselors and clients review the results of the questionnaires and discuss the client's career development process in depth.

Assessment of cognitive variables is focused on uncovering cognitions that might help or hinder the career development process. Commonly assessed cognitive variables include dysfunctional career beliefs (e.g., "There is one perfect job for me") and career self-efficacy. Once they are known, dysfunctional career beliefs can be corrected and career self-efficacy can be enhanced.

Although assessment interpretation can provide objective and illuminating information, care must be taken to integrate the information provided by standardized assessments with other information on the client's experiences, preferences, supports, and barriers.

### **Group Career Counseling**

Group career counseling represents a popular option for clients seeking help for many types of career-related issues. More specifically, group career counseling is a multisession group experience in which participants may focus on both the pragmatic aspects of career-related issues (e.g., deciding upon a career) and the members' emotional reactions to such issues (e.g., feelings of anxiety or interpersonal concerns). Group career counseling allows participants some of the same therapeutic benefits of individual career counseling, but also provides opportunities for discussion, support, and validation among members.

Career counseling groups are often hosted by community counseling centers, university counseling and career centers, and professional career counseling clinics. These groups may range in size from approximately 8 to 12 members, although they may field smaller or larger numbers depending upon factors such as the purpose of the group or resources available.

Career counseling groups are typically led by a trained professional psychologist, social worker, or counselor. These groups typically meet once or twice per week and may terminate after a set number of sessions or continue indefinitely, allowing members to come and go as their needs are met.

Further, career counseling groups vary in terms of the structure provided. Some may be quite structured with a set agenda for each meeting (e.g., receiving interest inventory feedback, learning about the career decision process, discussing sources of support for career plans, preparing resumes). Others are much less structured and emphasize the processing of group members' emotional reactions (e.g., dealing effectively with career-related anxiety).

### **Group Assessment Interpretation**

Group assessment interpretation is a focused form of group career counseling in which the primary purpose is the administration and interpretation of the results of one or more career-related assessments. For example, a group may convene to interpret a specific assessment, such as the Strong Interest Inventory, or may review a broader battery of inventories and tests measuring aptitudes, values, and personality traits.

These groups share some similarities with both individual assessment interpretation and group career counseling. However, they differ from individual assessment in that the participants do not necessarily receive individualized interpretation or consultation within the group setting, and they differ from group career counseling in that the goals of the group are relatively focused on interpreting the results of formalized assessments. Furthermore, group assessment interpretation is typically confined to one or two sessions, while group career counseling often extends for multiple, regularly scheduled sessions.

A group assessment interpretation session should be led by a professional who meets the minimum qualification requirements for the administration and interpretation of the assessments being used. Beyond these requirements, the leader should also maintain a good understanding of each assessment's psychometric properties as well as an awareness of the prospective areas about which group members typically inquire.

A group assessment interpretation session will often begin with a discussion of the purpose of the assessment, including how assessment results should be incorporated into a broader program of career guidance. The group members may or may not actually

complete the assessment(s) within the group setting. Upon inventory completion and scoring, the group moderator will initiate a detailed interpretation of the assessment results, including scoring procedures, normative information, and possible implications of specific results.

Although group assessment interpretation is not an appropriate environment for discussing the myriad individual concerns that may arise from inventory results and general career issues, group members receiving inventory results can often experience strong emotional reactions. These individuals are often referred to individual counseling as appropriate.

### ***Career Workshops***

Career workshops are a structured set of activities in a group setting that allow participants the opportunity to develop particular skills or complete a specific task, typically within one or two sessions. Career workshops are often difficult to distinguish from structured career groups. Career groups emphasize enhancing group member communication on a variety of topics. Career workshops, however, focus on providing information concerning a single topic. Typical career workshops might, for example, assist members in deciding upon a college major, developing interviewing skills, creating or enhancing a resume, or learning how to begin professionally networking.

Similar to group career counseling, career workshops are typically hosted by university career centers, community counseling centers, and professional career counseling clinics. Professional organizations may also offer their members career workshops, often as part of a broader program, such as an annual conference. A workshop may last less than an hour, extend through several multihour sessions, or even span multiple days. Although a licensed professional may host a career workshop, a trained staff member or an individual familiar with the workshop's topic may just as often deliver them. For example, a corporate human resources representative may present a workshop on effective interviewing skills or a practicing professional may speak about emerging opportunities in his or her career field.

### ***Career Classes***

Located primarily within college settings, career classes offer participants the opportunity to gain information about the world of work as well as explore their

own interests, aptitudes, and values. Goals of particular classes may vary, but often include learning about theories and career-related information sources, exploring relevant academic majors, gaining self-knowledge, and learning job search skills and strategies.

Career classes may or may not bear credits toward degree attainment and may be taught by faculty in an academic department (e.g., psychology) or by counselors from the school's career center. Participants typically come from the hosting institution's student body, but alumni and nonaffiliated individuals may also enroll.

Like more traditional academic courses, career classes often have a syllabus, required readings, and graded assignments. In addition, they typically extend over the duration of the school's regular academic period (e.g., a semester or quarter) and meet once or twice per week. A typical class session may include a lecture component with topics such as major career development theories or job-search strategies and a process component wherein students discuss the lecture or their ongoing career activities. In this way, career classes incorporate elements that appear in both career counseling groups and career workshops and may also include assessment administration and interpretation. However, these classes do not typically include the therapeutic components featured in individual or group career counseling.

### ***Computer-Assisted Career Guidance Systems***

Computer-assisted career guidance systems (CACGS) are computer programs designed to simulate the career counseling process by providing career assessments, occupational and educational information, and tools for making decisions, planning, and beginning a career path. CACGS are often used as tools for individual exploration that supplement and build upon career counseling.

Some commonly used CACGS include CHOICES, DISCOVER, and SIGI PLUS. Each of these systems has specific versions targeted for youth, college students, and adults. Each version offers interest, ability, and value assessment tools. Based on assessment results, these systems generate occupational alternatives. System users can also access specific information on occupations generated as well as on other occupations of interest.

System users are also presented with the educational requirements of each occupation they explore.

CHOICES, DISCOVER, and SIGI PLUS contain detailed data on technical, undergraduate, and graduate educational institutions, including majors offered and availability of financial assistance. Once system users have explored occupational and educational information, DISCOVER and SIGI PLUS present information on making career decisions. All three systems offer information on career planning, including how to write a resume and build a professional network.

While CAGS are user-friendly sources of career and educational information, their use is somewhat limited. Access to CACGS requires both computer access and affiliation with an institution that subscribes to a specific system. Not all schools, colleges, vocational bureaus, and universities can afford to subscribe to a CACGS, and not every client has the necessary Internet access. For clients who are able to use CACGS, these computer systems remain comprehensive, up-to-date sources of valuable information and self-knowledge.

### ***Counselor-Free Interventions***

Counselor-free interventions are activities in which individuals use resources other than a career counselor to obtain and evaluate information related to career development. People participate in counselor-free interventions on a daily basis. They might talk with others about their interests, work personalities, values, skills, preferred occupations, and career aspirations. Such conversations can occur as informal interactions, structured informational interviews, job shadowing, or professional networking.

In addition to talking with others, people might seek out published career information. Many libraries and bookstores contain printed guides to career development. There are also several Internet databases of occupational information. Examples include Web sites maintained by the United States Department of Labor that provide detailed descriptions of occupations, requirements, salaries, career paths, and related jobs. Computer-assisted guidance systems can also be used in a completely self-directed way, and various tools have been developed by professionals to aid people in self-directed career exploration activities (e.g., the Self-Directed Search).

Nonetheless, counselor-free interventions tend to be informal, self-directed, and completed without the assistance of a professional counselor or psychologist. Although such individual career development works

for many people, its main disadvantage is that people might not be aware of the broad array of career resources and tools available to them. As a result, they may base career decisions on quickly gathered or incomplete information. For this reason, the effectiveness of counselor-free interventions has been called into question.

### **Effectiveness**

A great deal of research has accumulated on the effectiveness of various career interventions. Commonly measured outcomes include the certainty of the client's occupational choice, the amount of information gathered, the number of new options generated, the success of obtaining employment, the overall satisfaction with career outcomes, and the counseling process itself.

One means of assessing the effectiveness of an intervention is to calculate its effect size, which is an estimate of the strength of an intervention's effect. For example, if 50 individuals received career counseling and 50 others did not and more of the former group actually found jobs, the numerical difference between the two groups could be considered an estimate of the effect size of the intervention. Although there are several statistical methods used to estimate effect size, one common method is to calculate Cohen's *d*, which is defined as the difference, in standard deviation units, between the means of intervention group and control group outcomes. When  $d = .5$ , for example, the intervention group improved half of a standard deviation more than the control group.

Furthermore, researchers have been able to aggregate the results of multiple studies using a procedure known as meta-analysis. Rather than evaluating an intervention's effect size based on a single study, researchers calculate a combined effect size from the data of many studies, thus producing a more compelling result. Although meta-analytically derived effect sizes can vary substantially, most studies have concluded that career interventions do exert a measurable effect on career outcomes. For example, a study by Susan Whiston, Briana Brechesisen, and Joy Stephens cited three separate meta-analyses that found a large range of career intervention effect sizes between 0.34 and 0.82. These meta-analytically derived outcomes can vary based on many factors, including the type of intervention (e.g., structured or unstructured group), the outcome investigated, or the statistical procedures used.

Despite the variance in effect sizes, two general conclusions can be drawn about career interventions. First, counselor-directed interventions appear to produce demonstrably better outcomes than self-directed interventions. The typical range of effect sizes for counselor-free or self-directed interventions are  $d$ 's from .10 to .11, while those associated with counselor-led interventions range from .34 to .82. Thus, career interventions are, without a doubt, effective means of helping clients explore options, make decisions, and find work.

Second, despite these findings, not all interventions involving counselors may be equally effective. Individual career counseling, individual assessment interpretation, career classes, structured groups, and workshops appear to be more effective on average than unstructured group career counseling, group assessment interpretation, and self-directed CACGS, although the effectiveness of computer guidance systems seems to improve substantially with counselor involvement.

A growing body of research concerning elements of effective interventions has shown that career interventions are most effective when they are (a) directed at older adolescents and adults, (b) between four and five sessions in length, and (c) include the critical components of journaling, goal setting, individualized feedback, information gathering, modeling, and support building. Thus, despite variability in the statistical procedures used, the outcome variables evaluated, and the actual effect sizes themselves, research consistently demonstrates the effectiveness of counselor-directed career interventions. The exception is unstructured groups, which consistently demonstrate meager effects on the types of outcomes that are the focus of most career interventions.

### Future Implications

It appears that most types of career interventions for choice making and job finding difficulties are demonstrably (but sometimes modestly) effective. Thus, people seeking help with self-understanding, job-related information, developing more or fewer occupational possibilities, career decision making, resume development, interviewing skills, and job search strategies can be assured of receiving at least some help with these important vocational difficulties via individual and structured group counseling, workshops, classes, and counselor-assisted, computer-directed guidance systems.

There is, however, much that still needs to be learned to ensure maximum benefit for the widest variety of help seekers. There is virtually no research, for example, that has tested the effectiveness of any form of career intervention for people seeking help for job dissatisfaction. There also appear to be few studies examining the effectiveness of current career interventions for people who have pervasive problems in decision making and problem solving. Whether current career interventions are effective with these people is unknown at this time.

Perhaps most important, there has been growing recognition in recent years that career interventions need to attend more fully to the role that clients' culture, gender, race, ethnicity, sexual orientation, and nationality have on the types of choices they make (and are able to make) and their ability to find satisfying work. There is evidence, for example, that the work choices of many Asian Americans are substantially more influenced by their families than their own personal interests, especially for those who are less acculturated into mainstream U.S. society. There is also clear evidence that people in lower social classes, people of color, and women experience more barriers to occupational choice, attainment, and success than do people of higher social classes: Whites and men. Thus, more data are needed on the effectiveness of career interventions with different groups in order to provide maximally effective career service to the widest array of clientele. Particularly needed is research that would allow counselors to target their interventions to the most pressing, career-limiting issues that the poor and marginalized bring with them to counseling and to factors that would most facilitate these clients' abilities to find more satisfying work. Finally, more research is needed on the cross-national effectiveness of career interventions. The interventions that were described in this entry were developed from a largely Westernized, individualistic worldview. More research is needed on career interventions and their effectiveness in cultures and countries in which collectivism is the dominant cultural value. A pressing question for future research is whether the types of interventions described in this entry can be adapted for these cultures, or whether wholly new culturally specific interventions are needed.

## CAREER/LIFE

---

The traditional view of career, what one does on the job at work and the sequence of work-related positions throughout a person's work history, has given rise to a holistic paradigm called career/life that includes the time and energy put into multiple roles simultaneously played throughout one's life. Each

role has the potential of positive or negative consequences for the other roles being played. This career/life paradigm provides numerous outlets for meaning making and self-expression, and it identifies one major outlet, specifically the work role, for money making and sustenance.

### Emergence

Career/life first emerged in the 1970s as theorists and practitioners sought a new model and language (career/life or life/career) to more effectively describe and deal with the realities of individuals struggling with problems associated with balancing work and other life roles such as homemaking, marriage, parenting, and attending school to either enter or advance within the labor market. Many of these persons were midcareer changers, some of whom were women labeled as displaced homemakers and enrolled in women in transition programs. The new term, career/life, coined by E. A. Colozzi in 1977 and reported by E. A. Colozzi and F. P. Haehnlen in their work in Hawaii and the Pacific Basin Rim region, was initially utilized for older adults in transition and later expanded to younger students in college and school-aged youth. Perhaps the most articulate and visually appealing representation of this model is D. E. Super's life/career rainbow that depicts the nine major roles played by people throughout the life-space and life-span continuum of their lives. His conception of the term life/career and subsequent writings have introduced many graduate students to this new paradigm as they are taught how to effectively assist their clients with making decisions about work and life roles.

### Intertwined Career and Personal Issues

Paramount in the early development of this paradigm was recognition that people's lives were complex and woven together with rich stories across life roles that provided important threads of relevance, informed decision making, and were all part of a continuous life journey that involved constant change and multiple transitions. Career and personal issues were now seen as intertwined, as they always have been. Work situations and relationships affect nonwork roles, and all of the nonwork roles directly affect the work role, including productivity and job satisfaction.

A divorce or unexpected death of a spouse can trigger a major transition for a woman who has primarily

been a homemaker and finds herself trying to support her three children as a single parent while taking classes at a community college to prepare for employment. Suddenly the old rules are no longer relevant, and dramatic changes may have occurred across several life roles requiring adjustment, coping skills, and a discovering of a whole set of new rules for survival during her continuing life journey.

### **Vocational Guidance Roots**

This paradigm shift has challenged the vocational psychology and the career development professions to better understand vocational behavior and to develop effective interventions that are relevant to this context of career/life. A brief review of the history of vocational psychology and vocational guidance will help one understand the emergence of career/life during the past 30 years.

In a comprehensive account of the antecedents that formed vocational psychology's foundation, origin, and emergence, M. L. Savickas and D. B. Baker describe vocational psychology as a specialty within applied psychology that advances the scientific research and knowledge about vocational behavior resulting in the development and improvement of career interventions. Its prehistory is rooted in the early stages of vocational guidance that is linked to the emergence of large commercial cities in which the factory system shifted the American economy from agriculture to manufacturing accompanied by industrialization, urbanization, and immigration during the 1800s.

Research by Savickas and Baker describes how the change in population distribution gave rise to many problems related to unemployment, alcoholism, delinquency, and crime, all of which prompted the establishment of the first Boston branch of the Young Men's Christian Association (YMCA) in 1851 to improve the spiritual condition and mental culture of young men. This effort eventually evolved into a combination of counseling and placement activities in conjunction with vocational training programs for youth at a time when educators became interested in individual differences and in addressing industry's need for more effective ways of matching people to new occupations.

The vocational guidance movement and the establishment of the profession, with the formation of the National Vocational Guidance Association in 1913 that

has evolved into the National Career Development Association, is almost 100 years young. It was born in 1909 with Frank Parsons in New England, specifically Boston, Massachusetts. Parsons, a Boston University law professor and leading civic reformer who championed the needs of Boston's poor population, is viewed as the founder of vocational guidance because his three-step paradigm of increasing self-knowledge, providing occupational information, and matching self to job (person to environment or P-E) using true reasoning is a conceptual model on which the field still rests, according to Savickas and Baker.

### **Person-Environment Matching Across Roles**

The career/life model successfully incorporates the Parson's P-E matching process for work-related decisions throughout the 7 to 10 job changes in several unrelated career areas most persons will experience in their work history. Additionally, it facilitates similar P-E matches across multiple life roles as individuals make choices about education, spousing, parenting, volunteer, and leisure activities, all of which affect each other and have the possibility of providing a sense of meaning and purpose.

The career/life model brings relevance to the learner role for students when they understand how the learner role and worker roles are closely connected. This can increase motivation and therefore increase student involvement and retention. Adults can use this paradigm to better understand the normal stressors involved in trying to balance parenting, work, and spousing activities to keep their relationships vibrant and healthy. Workers who are considering retirement now have an effective perspective for remaining active and healthy both emotionally and physically as they sort out leisure and volunteer activities that still provide appropriate and fulfilling P-E matches in nonwork roles. Even young students in K-6 settings can use this model to better understand the importance of developing good work habits in their "jobs" at school—their learner role—as a way of preparing themselves for the next grade level and subsequent school-to-school or school-to-work transitions. A major benefit of career/life, perhaps the most important, is the opportunity for people to realize the multiple ways it is possible to experience meaning and purpose through activating combinations of several career/life roles, one of which can be work.

## Future Challenges and Directions

The career/life paradigm is a response to societal changes resulting from further involvement with the information age. These include family structural changes where both spouses are often working while raising a family and acting as caregivers to aging parents, high divorces rates resulting in more single parents, increased stress related to work and nonwork roles, major technological advances often accompanied by new jobs and different ways of working, globalization, and the desire among many people to search for more meaning and purpose in their work and more balance in their lives as documented by E. A. Colozzi and L. C. Colozzi.

Some, such as D. L. Bluestein, have suggested that the career development field today has neglected the poor and focused mostly on those who are active participants in our educational systems and labor markets. This statement is probably very true, and more needs to be done with this population including the development of public policies that effectively deal with the career development needs of the poor.

Exciting challenges for the field of vocational psychology include initiating important research to advance knowledge about these issues, measuring career interventions, and informing public policy. Equally exciting challenges for the career development profession include promoting excellent career development interventions to effectively serve students in K–12 and postsecondary settings, workers seeking job changes, the unemployed (including the homeless, special needs populations, and other disenfranchised groups), workers planning retirement, and persons dealing with career/life conflicts across multiple life roles.

Perhaps the most important and exciting challenge is to strengthen the dialogue between the vocational psychology and career development professions so excellent research can inform and promote excellent career development practices that effectively facilitate the career/life decisions all people make.

## CAREER MASTERY INVENTORY

---

The Career Mastery Inventory (CMAS) evolved from the Career Adjustment and Development Inventory (CADI), a measure that was developed by John Crites as a means of assessing important facets related to career adjustment and development in early adulthood. Accordingly, six developmental tasks associated with the establishment stage of career development were identified. The establishment stage is typically defined as being between the point of occupational entry and midcareer. The CMAS consists of two parts. The first part assesses mastery of the developmental tasks. The second part assesses the ability to cope with problems in the work place.

The first part of the CMAS consists of 90 items that make up the subscales that reflect the six tasks:

(1) Organizational Adaptability involves the process of becoming socialized to the expectancies of the work environment, (2) Position Performance refers to learning the duties and tasks associated with a job, (3) Work Habits and Attitudes involves being dependable and receptive to supervisory feedback and having a positive attitude, (4) Co-Worker Relationships involves being cordial with others and dealing with interpersonal conflicts as they occur on the job, (5) Advancement involves promotion within the organization, and (6) Career Choice and Plans involves establishing goals and identifying a career path to follow. These scales are ordered along the sequence in which they would be encountered developmentally. Thus, the CMAS provides a series of developmental tasks that gauges an individual's level of adaptability during the establishment stage. Theoretically, mastery of these six tasks results in success at work and job satisfaction. A total score provides an overall index of career adjustment.

The second part of the CMAS consists of 20 open-ended items that assess how well a person can cope with problem situations on the job. These items reflect thwarting or barrier conditions that occur in the work place. Scores on this part of the CMAS reflect how well a person managed each situation. Responses to these items are scored on three levels of adjustment: *integrative*, *adjustive*, or *nonadjustive*. An integrative response indicates that the person was able to remove the barrier condition and reduce tension and anxiety. An adjustive response indicates that the person was able to reduce tension and anxiety, but was unable to remove the barrier condition. A nonadjustive response indicates that neither the barrier condition was removed nor tension and anxiety reduced.

The CMAS can be either hand or machine scored. Raw scores are plotted on a profile and matched against the corresponding standard score. Further information regarding scores can be found in the *CMAS User's Guide*, which also includes case study illustrations. CMAS scores can be used to benchmark how well individuals are progressing in their career development when compared to their peers in an organization, thereby providing a means of identifying those who may require intervention in their career development.

## CAREER MATURITY

---

Career maturity is defined as the degree to which individuals are prepared to make good educational or vocational decisions. It is usually seen as dependent on their knowledge of themselves and of the world of work, their ability to make decisions, and a positive attitude toward making career decisions. It is developmental in nature, following an individual's growing maturity in all life areas. Frank Parsons, generally considered to be the father of career development, saw career maturity as encompassing a clear understanding about oneself, knowledge of the requirements of different occupations, and true reasoning on the relationships among these. The term *career maturity* was first promulgated by Donald E. Super, and many authors have used it subsequently in developing career counseling assessment instruments and career counseling processes and procedures.

Counselors and others who run career programs in schools and other institutions that are developmental in nature often consider career maturity to be an objective of these programs. This is in contrast to programs that see a career decision as the desired outcome of intervention.

Career maturity may encompass the ability to make good career decisions or the state of having made these decisions. The term *good* is used as a shortcut for the variety of elements that enter into career decision making. These elements include areas of self knowledge, such as knowing one's values, understanding one's interests, being aware of one's temperament, and thinking about one's lifestyle preferences. The term includes knowing about one's strengths and weaknesses, abilities and liabilities, skills, aptitudes, learning style, and motivation. The elements of good also include knowledge of the world of work, such as knowing about the requirements of various occupations—training or formal education, apprenticeship, on the job training, and so forth. It includes knowledge of the opportunity structure, for example, is the field growing

or declining? How many potential openings are there in an individual's desired geographical location? It includes understanding how to find out occupational information. And of course it basically means knowing what the work entails.

A positive attitude toward making a career decision is implicit in the concept, and that attitude includes individuals' confidence in their knowledge and skills in the arenas outlined above including confidence in their ability to make good decisions. This often derives from having had successful previous experience in decision making.

Recently, there have been questions about the appropriateness of the concept in a world where individuals must frequently reassess their career plans and objectives. Some, including notably Super himself, have stated that career flexibility or adaptability may be more fitting descriptors for individuals who are capable of being self-directed in their career decision making.

## CAREER MATURITY INVENTORY

---

The Career Maturity Inventory (CMI) is a 50-item standardized measure designed to assess the process of how adolescents and adults approach career development tasks. John Crites developed this measure in the 1960s as the Vocational Development Inventory to assess the readiness attitudes of students in making appropriate vocational plans. It became the CMI in 1973 and was

enhanced to include career planning competencies, including knowledge of self and the world of work. The CMI was revised in 1978 and most recently in 1995. Potential uses of the CMI include researching career development, needs assessment, career counseling, and program evaluation. Counselors may supplement interpretations by using an additional guide, the *Career Developer*, to explain correct answers.

Crites's conceptualization of career maturity is based on Donald Super's theory of career development, which emphasizes general factors related to realistic career choice content and process. Based on longitudinal analyses, items were selected to differentiate adolescents across a developmental continuum toward higher levels of career maturity. Higher CMI scores identify individuals with mature career decision-making approaches resulting in readiness to make informed career plans.

Consistent with Crites's model of career maturity, the original CMI assessed five competencies (self-appraisal, occupational information, goal selection, planning, and problem solving) and five attitudes (decisiveness, involvement, independence, orientation, and compromise). The 1995 CMI collapsed these into broader dimensions measuring competence, attitudes, and career maturity total because the previous more specific scales yielded low reliabilities that were not readily incorporated into counseling practice. Clients respond to statements drawn equally from each of the original scales to address each construct. The original CMI used a true or false item format, whereas the current version uses an agree or disagree format. A sample Attitudes item, "I seldom think about the job I want to enter," reflects one's involvement in the process. The competencies section comprises 25 statements in which respondents appraise the appropriateness of content reflected in brief narratives.

Over 3 decades of research, including 2,000-plus investigations, have shown that CMI scores increase throughout adolescence and as the result of interventions. However, the individualistic nature of career maturity has raised questions regarding cross-cultural validity and counseling utility. For example, Asian Americans who typically represent a collectivistic orientation tend to score lower on the CMI because of their more interdependent decisional style. Although extensively researched, ongoing attention to examining psychometric qualities of the revised CMI is warranted.

Recently, the concept of career maturity has been expanded and termed career adaptability to encompass adult career concerns. In their 1995 revision, Crites and Mark Savickas sought to strengthen its practical relevance, to update standardization samples, and to minimize cultural bias in item content. Several items were modified or deleted to increase applicability with postsecondary clients. In addition, they shortened administration time, increased content relevance to adults, collapsed the subscales into broader dimensions, produced a companion guide to enhance counseling applications, and improved scoring options. Although some research has been conducted on the revised CMI, concern about the internal consistency of scales persists. Nonetheless, the rich empirical and theoretical foundations of the CMI warrant continued use in counseling and research.

## CAREER OCCUPATIONAL PREFERENCE SYSTEM

The Career Occupational Preference System (COPSystem) is a coordinated career guidance program consisting of three assessment instruments all keyed to eight major career clusters. The three assessment components are the COPSystem Interest Inventory (COPS), the Career Ability Placement Survey (CAPS), and the Career Orientation Placement and Evaluation Survey (COPES) and their accompanying interpretive materials. Interpretation of the three assessments is organized around an easy to use group of eight occupational clusters representing all possible jobs in the world of work. The COPSystem measures interests, abilities, and values in terms of these eight major career clusters: science, technology, outdoor, business, clerical, communication, arts, and services with five of the eight cluster results representing both professional and skilled-level occupations for a total of 14 clusters. The COPSystem assessments are designed to assist individuals in the career exploration and decision-making process.

The COPS consists of 168 job activity items, and examinees respond to these items according to their degree of like or dislike for each item based on a 4-point scale from *like very much* to *dislike very much*. The norms are based on samples of high school and college students throughout the United States and are updated every 2 to 5 years. The COPS is a valid and reliable instrument. Alpha reliability coefficients range from .86 to .92, and validity has been established through a long-term study demonstrating that 64% of students were in a job or college major that matched one of their three highest interest areas from 1 to 7 years after taking the COPS.

The CAPS consists of a battery of eight 5-minute ability tests that provide a comparatively brief and cost-effective measure of ability for career development. The eight ability tests in the CAPS are Mechanical Reasoning, Spatial Relations, Verbal Reasoning, Numerical Ability, Language Usage, Word Knowledge, Perceptual Speed and Accuracy, and Manual Speed and Dexterity. The CAPS scores are reported based on three norm groups; grade levels 8–9, 10–12, and college. Examinees receive scores for abilities as compared to each of the 14 career clusters reported on the COPS, demonstrating areas of

strength and weakness in terms of ability. The CAPS test–retest reliability coefficients range from .70 to .95 and predictive validity studies show that ability scores are significantly related to subsequent career choice.

The COPEs is a measure of personal values that reflect major dimensions representing vocational motivation based on the following scales: Investigative Versus Accepting, Practical Versus Carefree, Independence Versus Conformity, Leadership Versus Supportive, Orderliness Versus Flexibility, Recognition Versus Privacy, Aesthetic Versus Realistic, and Social Versus Reserved. Each dimension is measured by two-choice, paired comparison items, and scores are reported for each values scale as well as related to the COPSys system career clusters. The reliabilities range from .70 to .83, and a preliminary follow-up study found an 89% hit rate for work values matched to subsequent career or college major choice.

The benefit of the COPSys assessment program is that the three most key components of choosing a career are combined on a single profile allowing the examinee to consider a complete profile and make an informed decision on how to move forward in the career exploration process.

## CAREER PLANNING

---

Career planning refers to the process of making educational and career choices based on knowledge of self and of the environment. The purpose of career planning is to encourage individuals to explore and

gather information about various educational and career opportunities thus enabling them to develop realistic career goals. Career planning is an ongoing activity that should be implemented as early as the middle school years and extend into adulthood. The career planning process can be divided into four stages. These stages include (1) self-assessment, (2) knowledge of academic-career options, (3) in-depth evaluation and goal setting, and (4) career plan implementation.

Self-assessment refers to an individual's ability to gather information about his or her interests, skills and abilities, values, and personality type. Examples of questions to consider at this stage include the following: What types of work and school-related courses and activities do I enjoy? What can I do well? What types of skills have I gained through various curricular and cocurricular experiences? What values do I consider important in my preferred career? Many of these questions can be answered through career assessments such as the Kuder Career Planning System, Strong Interest Inventory, or Self-Directed Search.

Knowledge of academic-career options refers to an individual's ability to gather information about the world of work. Knowledge of specific jobs, occupations, and organizations; work conditions; required education; job outlook; and chances for advancement are important factors in choosing the right career. Individuals can explore possible careers using a number of different resources such as the Occupational Information Network (O\*NET), *Occupational Outlook Handbook*, or computer-assisted guidance systems. Other activities could also include spending time with adults who are engaged in occupations related to one's interests, job shadowing, volunteer work, and discussing one's educational plans with parents, teachers, and guidance counselors.

In-depth evaluation and goal setting refers to an understanding of how to make decisions based on the information one has gathered in the first two stages of career planning; an awareness of the factors that may impact one's ability to implement one's decisions; and the setting of short-, medium-, and long-term goals. During this stage, individuals may want to consider questions such as, Do my interest, skills, and values match those of the occupation I've selected? What schools offer the training that will be needed to pursue my career of interest? How long will it take me to

complete the education required of my career of interest? Are there other occupations that I should consider as alternatives?

Finally, the last stage of the career planning process is career plan implementation, which involves making an initial choice and taking steps toward reaching career goals. The primary focus of this stage is on job and educational preparation. Individuals at this stage should make deliberate efforts to (1) apply to various education and training programs, (2) gather information on specific companies, (3) develop a job search strategy, (4) develop résumés and cover letters, and (5) prepare for job interviews.

## CAREER PLANNING SURVEY

---

The Career Planning Survey is a paper-based career assessment system designed to help students in Grades 8 through 10 identify and explore personally relevant occupations and high school courses. The assessment elements consist of an interest inventory, an inventory of ability self-estimates, and two optional academic ability tests. In addition, students can complete checklists assessing their work-relevant experiences and the characteristics they want in a job.

Counselor materials encourage the use of the Career Planning Survey in group settings to teach students how to gather and consider self and occupational information essential to the exploration of educational and occupational options.

The Career Planning Survey is published by ACT. It is one of several ACT programs (such as PLAN, EXPLORE, and DISCOVER) that use the ACT World-of-Work Map to graphically show students how their assessment results relate to occupations and how occupations relate to each other. The Career Planning Survey was introduced in 1997.

### Features

#### Assessments

The revised Unisex Edition of the ACT Interest Inventory (UNIACT) assesses preferences for work-related activities. The 90 items emphasize activities that are familiar to people either through participation or observation. Scales are organized according to the six types of basic interests described in John Holland's theory of careers.

The Inventory of Work-Relevant Abilities (IWRA) obtains informed self-estimates for 15 abilities shown by research to differentiate occupational groups. Example abilities are mechanical, sales, leadership, and scientific. Scales are organized according to the six types of basic interests described in John Holland's theory of careers. As described in the *Career Planning Survey Technical Manual*, IWRA has been empirically shown to improve the career exploration validity of tested abilities.

Two optional academic ability tests assess level of development in reading skills and numerical skills. Results are nationally normed by grade level.

#### Score Report and Student Materials

The unique Career Planning Survey score report is the only paper-based score report that visually links both interest and ability results to occupational options. Both UNIACT and IWRA scores are converted to directional information on the research-based World-of-Work Map, permitting students to visually compare their interests to their abilities and to see career options in line with each.

A booklet accompanying the score report guides students to information on more than 500 occupations.

These materials use a step-by-step approach designed to broaden career horizons while simultaneously providing focus for career exploration. As described in the *Career Planning Survey Counselor's Manual*, panels of high school students and counselors reviewed assessment and student materials for age appropriateness.

### **Japanese Edition**

The Career Planning Survey—Japanese Edition was introduced in Japan in 1998. There are currently two versions: a paper-based version and an Internet version. It is used by college students to explore personally relevant occupations, and by adults in career transition. These products are jointly owned by ACT and Nippon Manpower Co., Ltd.

## **CAREER RESOURCE CENTERS**

---

A career resource center (CRC) refers to a physical facility and to the location of materials, resources, and personnel delivering career services to individuals and groups. A CRC is typically located in the career center, counseling center, human resources office, library, or training and development unit of an organization. In contrast, a career center is an administrative unit of an organization—for example, school, business, or agency—that employs staff who deliver a variety of career programs and services. Comprehensive career centers provide career counseling and assessments, experiential career opportunities such as internships and cooperative education, educational and career

information, job hunting assistance, and employment information. They may also provide services to employers seeking to fill their hiring needs. Less comprehensive career centers may provide only some of these services. A career center would almost always include a CRC.

When the vocational guidance movement in the United States emerged in the early 1900s, the development of CRCs was one of its most tangible and lasting accomplishments. The roots of the movement sprang from the social reform and humanitarian activities in urban areas in the Midwestern and Eastern United States. CRCs were often located in settlement houses, which provided a variety of social services including vocational guidance to immigrants and others. Career counseling developed in the context of these CRCs. A distinguishing CRC feature was and remains the provision of resources and information about occupations, jobs, training, financial aid, employability, and career planning. This entry briefly reviews some of the characteristics of the first CRCs that have carried forward to the present time and describes the characteristics of modern CRCs.

### **The Development of Career Resource Centers**

Frank Parsons, generally regarded as the father of vocational guidance, at the turn of the last century created one of the first CRCs. His Vocation Bureau was located in the Civic Service House, a Boston settlement house that provided a variety of social and civic services to citizens and Italian immigrants. Parsons created this early CRC with a private grant provided by a wealthy Boston matron, and he formulated a technique for providing career counseling in this context. His book, *Choosing a Vocation*, was published posthumously in 1909 and included details about the resources, materials, and staffing of the Vocation Bureau.

With the passage of time, CRCs moved from community settings such as settlement houses mostly into colleges, universities, and high schools and less often into business organizations, governmental, and social service agencies. The Vocation Bureau, for example, found a new home at Harvard University. In educational settings, CRCs were typically housed in either a counseling center or a career planning and placement center. More recently, CRCs are most likely to

be located in a career center and provide the resources used by staff and clients to solve career problems and make career decisions.

The resources in a CRC can include inventories and tests, card sorts, books, descriptions of occupations or educational and training institutions, CDs and DVDs, pamphlets, clippings, Web pages, instructional modules, multimedia resources, training materials, magazines, take-away materials (free handouts), and procedures for locating information or preparing for a job campaign, for example, resume writing and interviewing. Career counseling is another resource that might be available in a CRC, and professional counselors or paraprofessionals, sometimes called career development facilitators, could provide it. The intended outcome of using career resources, including career counseling, is client or customer learning and a change in career-related behavior.

Career resources can be grouped into three broad categories: (1) assessment instruments, (2) information sources, and (3) instruction. Assessment resources include instruments that enable persons to examine their self-knowledge, typically interests, values, skills, and abilities, in order to create information for career problem solving and decision making. These instruments may be used in a self-help format or with the assistance of a professional counselor.

Information resources describe the characteristics of occupations, education, training, and employment that individuals use to refine their career options. Occupational information describes the nature of work, the nature of employment, and the requirements for employment in occupations (e.g., accountant) and categories of occupations. Occupational information is also used to identify and learn about job targets in employment decision making. Educational information describes the nature of education or training, the nature of the institution or training provider, and admission to individual institutions or categories of institutions (e.g., community colleges). Employment information describes sectors, industries, employers, and positions in the job market.

Instructional resources are used to help persons clarify self-knowledge, knowledge of their options, and knowledge of the decision-making process. In this context, career counseling could be considered as a form of instruction. Instruction is related to career assessment and career information described previously, although several differences exist. For example,

instruction or counseling integrates several sources of information in a meaningful sequence designed to achieve a specific learning outcome, for example, a booklet on how to make a career decision. In comparison with assessment and information, instruction or counseling is a less commonly available type of career resource.

## **Career Resource Center Operations**

### ***Staffing and Operations***

Successful operations in a CRC require special management and administrative staff. A hierarchy of professionals, paraprofessionals, and support staff work together to maintain the library and resources and to provide effective career service to users. A media specialist or librarian should be available to manage the materials, and information technology professionals are needed to monitor computer software. A manager, often a professional counselor, should oversee CRC operations and provide supervision to the counselors and other staff.

The manager or consultant knowledgeable about all aspects of both career development and organizational structure, perhaps aided by an advisory committee, designs and implements the CRC program. After conducting a needs assessment, the manager proceeds to create a mission statement, design a program plan, coordinate existing programs, and ultimately run a pilot study prior to implementation.

### ***Budget***

A CRC budget varies according to the size, location, and complexity of the center, as well as the needs of the users. It typically includes funds for salaries, tests and inventories, furniture, equipment, technological support, books and materials, printing, subscriptions, staff training, and office materials.

### ***Location and Facilities***

As noted earlier, a CRC can be located in various settings, ideally in a high traffic area with easy user access. It is important that the site and facilities have interior open space with windows and have walls for displaying posters and signs directing users to resources. Facilities should include an ample amount

of shelf space and file cabinets to store the materials, as well as counseling offices, meeting rooms, study tables and chairs, display racks, bulletin boards, and a copier. With the advent of the Internet, CRCs have increased user access to materials and resources via the Web resulting in virtual CRCs.

### **Materials Acquisition, Management, Collection, Cataloging, and Evaluation**

Typically, the counseling staff and the media librarian or specialist are responsible for selecting, managing, and collecting materials for the CRC. It is crucial for these staff members to consider the population utilizing the materials most often, as well as the funds available to maintain, update, and acquire new resources. Both the staff (counselors and professionals) and the community should be able to locate and use the resources with little or no assistance if necessary. Scores of vendors—for example, professional associations, commercial publishers, government agencies, news organizations—offer materials for a CRC, materials that include many free and low-cost products. Some professional associations, such as the National Career Development Association (NCDA), have established guidelines for evaluating career information and resources.

### **Marketing and Public Relations**

A CRC requires continuous marketing of programs and resources. In a college or university setting, for example, incoming students can be targeted as well as those in other transitions, for example, those about to graduate. A Web site and electronic mailing lists are used in marketing along with varied print media. Conducting workshops at various locations and writing articles for community publications can disseminate news of CRC programs. These marketing techniques should explain the CRC's mission and objectives as well as how users will be treated when they seek services.

## **CAREER SERVICES MODEL**

---

A difficult task facing career counselors concerns applying abstract career theories to concrete problems presented by clients. Over the years, counselor educators have voiced concern about their trainees' ability to accurately assess client problems and make sound clinical decisions. In practice, novice career counselors also become perplexed by the multitude of career methods and materials available to them. Conceptualizing a client's career problem requires a map to guide the selection of appropriate career services, and vocational scholars have proposed diagnostic classifications of career problems. A recent theory-based classification by Savickas was designed as a matrix to strengthen the connection between theory and practice as well as to ease the transaction between researchers and counselors. This model, summarized here, elaborates upon the Savickas model for career services and offers a practical schema useful for counselors who provide career counseling services. This taxonomic model has two conceptual domains, interpersonal and intrapersonal, that each encompasses three developmental levels. These domains and levels constitute six career service areas: career guidance, career placement, career education, career counseling, career life-development, and career adjustment.

Career problem assessment begins by locating a career problem in one of two conceptual domains for further exploration. Within the interpersonal domain, there is active negotiation with the environment or a high degree of contact with other persons. The implicit problem in career guidance involves making a career choice. The counselor often explores whether the client wishes to begin a new job or change an existing position. The objective is to assist clients in learning how to explore matches between their clarified self-concept and jobs. The implicit problem in career placement involves starting a career. The counselor is concerned with how clients attain their chosen positions. The objective is to assist a client after he or she has made an occupational choice: preparing and refining self-presentation behavior. The implicit problem in career education involves developing one's career. The counselor focuses on the individual's dispositions and problem-solving abilities.

The intrapersonal domain is growth seeking and discomfort reducing. It involves contact with one's feelings, emotions, and cognitions. The implicit problem in career counseling involves one's self-conception. The counselor explores the client's self-concept, approach to meaning making, and cognitive structure. The objective is to prepare a client to articulate and develop his or her vocational self-concepts and public identities and to develop career decision-making skills. The implicit problem in career development involves managing and coping with work. The counselor explores how the client has been and is adapting to multiple life roles in the context of work. A primary objective is to prepare a client to anticipate, become aware of, and cope with concerns arising within the stages of the career life span. The implicit problem in career adjustment involves adaptation to a career. The counselor explores how the client is adapting to thwarting conditions. The objective is to help a client adjust to unanticipated and unique events within his or her work position by developing coping skills and resilience.

Assessment begins with a focus on how a client experiences his or her career problems and aids in determining the experiential level of the presenting problems. Level A problems involve choosing an occupation (i.e., career guidance and career counseling). Level B problems involve preparing to enter a chosen occupation (i.e., career placement and career development), and Level C problems involve coping with a career (i.e., career education and career adjustment).

Career guidance shows clients how to gather information about themselves and the world of work.

Career counseling helps a client with intrapersonal barriers to career choice closure. Career placement helps a client develop and plan ways to attain a new position. Career/life development applies theories and measures to assist clients in coping with, preparing for, and managing concerns primarily related to balancing work with other life-role activities. Career education engages students and clients in discussion about their competencies such as planning and decision making, and fosters self-management attitudes such as future orientation and autonomy. Career adjustment explores client's work personality and work competencies.

Although not presented here, this model locates the major theories and common measures applied as they relate to the six service areas. As this framework aids in the understanding of a client's presenting career problem, it also serves to guide intervention planning, provides a perspective to guide further inquiry, and intends to stimulate necessary research efforts to investigate its effectiveness for counselors.

---

## CAREER STYLE INTERVIEW

---

The career style interview (CSI) consists of six questions and is the primary means of assessment for those

interested in applying the theory of career construction as developed by Mark L. Savickas. This theory helps individuals to find meaning in the nonlinear careers of today and is an expansion and clarification of Donald Super's life-span life-space approach to careers. An individual's career style is often an unspoken means of viewing and interacting with the world and especially with the world of work. The CSI, therefore, is a qualitative interview that serves to draw out the narratives that are active and present in a person's life while also providing objective feedback to foster clarification and delineation of one's themes. The measure often provides the crucial link needed for individuals to recognize their active life themes, tie them to their vocational behavior, and make their vocational decisions more effectively.

The counselor and the client collaborate through the CSI to identify, interpret, and construct what the person prefers, how the person copes, and why the person pursues what he or she does through work. In the terms of vocational psychology, the CSI provides a means of determining and then linking an individual's vocational personality, career adaptability, and life theme into an organized whole. This understanding allows the individual to see the unity of his or her motivations and the consistencies of the individual's past, present, and future career paths. The CSI is ultimately a tool designed to empower individuals through clarifying how their work can make personal meaning and matter to others.

## History

The CSI was initially developed by Savickas in 1989 as a measure to clarify life stories' relation to career choices and decisions. The instrument draws from several historical models of assessment including Adlerian and constructivist approaches. The model, however, values and uses narrative or self-stories to tie the career components together for the individual. Narrative story in this context is not an attempt to determine the future from the past, but is the process of actively making meaning and providing direction for the present and future. The assessment process reveals and then unifies the subjective and objective influences upon individuals' career trajectories and concerns, facilitating a link between their life motivations and passions and their career motivations and choices. Although the CSI was initially used with individuals uncertain of career choices, its ability to

bring to light a broad spectrum of career concepts has encouraged its use with a variety of career counseling issues.

## Process

The CSI measure is a qualitative interview that consists of six basic questions related to family, interests, role-models, and recollections. The questions examine the goal for career counseling, past and present nonfamily role models, reading and television preferences, hobbies, favorite sayings, preferred school subjects, and several early recollections. Responses to these questions are written down by the counselor in the client's own words. Upon completion of the questions, the interviewer then uses the written notes to highlight the client's consistent themes. Consistent themes are identified through repeated verbs, words, phrases, and concepts expressed during the interview. The notes serve as a concrete reference point for the counselor and client to begin reflection and discussion about the content of the interview. The CSI process is a collaborative event where the counselor and client validate, construct, and refine the themes noted as a result of the questioning process.

## Personality

The process of validation often begins with reflection upon the vocational personality or the interest preferences of the client. Vocational personality relates to what an individual prefers to do and where his or her personal preferences may fit with the world of work. A typical framework used to conceptualize the individual's responses is according to John Holland a differential theory of vocational personality. Counselors often rely upon formal structured assessments to measure these preferences, but the CSI questions can provide the individual's primary Holland codes in an indirect manner. Using the Holland RIASEC (Realistic, Investigative, Artistic, Social, Enterprising, and Conventional) model as a framework, the counselor can often identify the two or three primary codes of the client from his or her narrative stories. The codes are often clearly expressed in the client's responses to the questions about school subjects, hobbies, and role models. The counselor usually overviews the Holland framework with the client and then discusses how the various preferences have been suggested in the responses to the CSI. This

information is processed with the client in an open discussion focused on delineating the primary codes and what the preferences may mean for the person.

Identifying individuals' Holland coding is not pursued simply to restrict their choices, but to provide new possibilities and more direction for future career pursuits and decisions. The coding can be used for a number of career purposes including validation of current or future career direction or highlighting the inconsistency of past or present work fields or positions. In addition, the CSI uses the Holland code to construct a success formula with the individual after the end of the interview. The client's code is used to develop a basic success formula statement using motivational phrases selected from a success formula grid and refined with the client. Phrases are suggested and a statement is constructed that provides a measuring stick that identifies what it takes for the individual to feel successful. This can then be used in making modifications to the individual's current position or in making decisions about work that would foster self-actualization. How the individual makes those decisions, however, is related to his or her career adaptability.

### ***Career Adaptability***

The career adaptability of the person is revealed through his or her narrative and clarified through further discussion with the counselor. An individual's CSI narratives will often indicate how the person interacts with or adapts to career developmental tasks, transitions, and setbacks. Career adaptability is conceptualized as consisting of four dimensions regarding career that include concern, control, curiosity, and confidence. Adaptive individuals are developing their attitudes, beliefs, and competencies in these four areas. Through the interview, the counselor often notes a lack of development in one or more of these dimensions and will discuss this with the person. The goal of the discussion is to develop a plan of action that will foster growth in the underdeveloped areas and increase the individual's career adaptability overall.

The CSI also seeks to identify the individual's early role models by asking directly and indirectly about them. Early role models are important to explore because they are conceptualized as solutions to the problems or challenges individuals faced in their early life. The role models often serve as a prototype for how one should make life and career decisions successfully. The CSI also views career as an

extension or an attempt of the individual to enact a self-concept, and role models relate to this purpose. Similarities and differences between the individual and the role models are explored, and this helps clarify some to the reasons for their selection. In addition, further discussion with the counselor about the role models frequently sheds light onto why a person pursues certain things through work. Early recollections also help to answer this question.

The end of the CSI includes several questions to illicit deeper projective stories related to earliest recollections or memories. The counselor using this technique is not assessing for factual truths, but is actually looking for repeated themes that permeate the individual's life and are expressed through his or her recollections stories. The stories that the individual selects and shares frequently provide the solution to the current career problem or demonstrate the strength needed to successfully navigate it. These stories can reflect fear, abandonment, or uncertainty, but they can also include joy, celebration, and support. The counselor notes the description and clarifies the emotions in the recollection, clarifying any relationship to the client's present career context. In addition to recounting the three recollections, the person is asked to title each with an active headline. These stories and their headlines are then used in conjunction with the rest of the client's narrative to identify deeper themes that permeate the individual's life.

### ***Life Theme***

The life theme concisely organizes the behavior of an individual and demonstrates the consistency of the person across time. It highlights a client's motivations and beliefs while also answering the why question behind his or her enactments both vocationally and avocationally. Life themes can often include a metanarrative of turning past pain into others' gain or turning a life preoccupation into an occupation. The themes frequently include motivations that need to be expressed or included in vocational decisions and commitments. When reviewing the overall data produced by the CSI, the counselor looking for the life theme is not necessarily focusing on the facts, but on the glue that seems to hold all of the facts together. The life theme underlies all of what has been shared by the individual and should pull all of the ideas together in a complete picture that clarifies the ruling passion of the individual's

life. It frequently communicates what is at stake in the person's life or what gives purpose and meaning to his or her work. The life theme discussion is a process of illumination that can take time and is often simplified by a thorough review of the notes where the counselor focuses upon repeated verbs, words, phrases, and themes. The condensed content then becomes the basis of the discussion to construct and validate the life theme of the individual. The CSI and the resultant narrative interpretation seek to clarify and refine the theme that permeates the individual's life with meaning and produces a life that matters to others as well.

Mark C. Rehfuss

## CAREER THOUGHTS INVENTORY

---

The Career Thoughts Inventory (CTI) is a theory-based assessment and intervention resource intended to improve thinking in career problem solving and decision making. The CTI measures dysfunctional career thoughts that may inhibit the ability to effectively engage in career decision making. The 48-item inventory is self-administered and objectively scored. The assessment is designed to be used by 11th- and 12th-grade high school students, college students, and adults who are choosing an occupation, choosing a major or field of study, seeking employment, or making an employment change.

The CTI is based on cognitive information processing theory, which states that effective career decision making requires effective processing of information in the four domains of self-knowledge, occupational knowledge, decision-making skills, and executive processing. The CTI draws on concepts from cognitive therapy specifying that dysfunctional cognitions have a negative impact on behavior and emotions. The CTI can be used to identify negative career thoughts that impede the effective processing of information necessary for career problem solving and decision making. The *CTI Workbook*, which accompanies the CTI, comprises cognitive restructuring activities similar to those used in cognitive therapy for depression and anxiety.

Items on the CTI are scored on a Likert scale with responses ranging from *strongly agree* to *strongly disagree*. The total CTI score reflects the extent to which individuals engage in thinking that may inhibit effective career problem solving and decision making. Higher scores are indicative of the presence of dysfunctional thoughts that may impede the processing of information necessary to confidently make an informed career choice. Lower scores reflect few dysfunctional career thoughts that negatively impact the career decision-making process and suggest overall readiness to engage in career decision making. Information on the standardization, potential for bias, readability, reliability, validity, and utility of the CTI is presented in the professional manual.

Three construct scales underlie the CTI: Decision Making Confusion, Commitment Anxiety, and External Conflict. Construct scale scores of the CTI enable practitioners to identify specific blocks that impede the processing of information. Mental health concerns such as depression and/or anxiety may also exist when

high scores are reflected in Decision Making Confusion and Commitment Anxiety. Similarly, high scores on the External Conflict scale may suggest family issues that would be beneficial to address. Individual items on the CTI may also be used as a stimulus for the client to verbalize internal and external barriers to decision making.

The CTI can be quickly administered and scored, easily interpreted, and readily integrated into a variety of counseling modalities. As such, it provides a cost-effective measure for use in career services in a variety of settings. The CTI has multiple uses and can be used as a screening tool, for needs assessment, and as a learning resource. The use of a limited number of scales on the CTI simplifies interpretation and enhances its usefulness in practice. When used in combination with the *CTI Workbook*, practitioners have access to interpretive information about the scales and materials for test interpretation. All of these contribute to easier integration into existing programs and services.

## CAREER TRANSITIONS INVENTORY

The Career Transitions Inventory (CTI) is a 40-item Likert format measure designed to assess an individual's internal process variables that may serve as strengths or barriers when making a career transition. For purposes of this instrument, the term *career transition* was defined as a situation in which any of the following kinds of career changes were being considered: (a) task change—a shift from one set of tasks to another set of tasks within the same job and same location (e.g., a software designer changes into software sales), (b) position change—a shift in jobs, with the same employer or a different employer (e.g., a secretary moving to a different department within the same company), or (c) occupational change—a transition from one set of duties to a different set that might include a new work setting (e.g., a farmer becomes a factory worker).

The fact that increasing numbers of individuals are making career transitions was a primary reason for creating the scale. Increased technology, labor force participation rates, and global change all contribute to the growing number of career transitions. Although the field of career development had numerous scales available to measure interests, skills, ability, and values, there was a dearth of scales to measure the barriers and supports adults have when making a career transition. The inventory was created to aid in the transition process by helping adults recognize the skills they bring to a transition as well as possible internal barriers that may serve as obstacles to the career transition process. All of the factors measured by the CTI are considered states, rather than traits, and thus are malleable to intervention.

The CTI was created and validated through factor analyses and a series of investigations examining the inventory's reliability and validity. Five distinct factors were found through factor analytic studies. These factors were Career Motivation (Readiness), Self-efficacy (Confidence), Perceived Support (Support), Internal-External (Control), and Self Versus Relational Focus (Decision Independence). These factors were found to have good internal consistency ranging from .66 for perceived support to .87 for readiness. Total scale alpha coefficients for the CTI are .85. Test-retest coefficients for the total CTI over a 3-week period was .84. The CTI has been found to correlate positively and significantly with age, marital status, length of time in the transition process, and five global

ratings of coping (i.e., perceived level of stress in the career transition process). In addition, enduring personality traits such as those measured by the NEO Personality Inventory have been found to predict career resources as measured by the CTI. For example, Openness to Experience from the NEO has been found to predict all five factors on the CTI, indicating that a willingness to try new things is an important variable in predicting how one negotiates the career transition process. The CTI has been translated into French, Italian, Mandarin, Japanese, and Korean. Additional psychometric work has been conducted in some countries to determine if the factor structure is the same.

## COGNITIVE INFORMATION PROCESSING MODEL

---

There is an adage, “Give people a fish and they eat for a day, but teach them to fish and they eat for a lifetime.” This wise maxim succinctly captures the

ultimate aim of the cognitive information processing (CIP) approach to career counseling—that is, enabling individuals to become skillful career problem solvers and decision makers. Through the CIP approach, individuals learn not only how to solve the immediate career problem and make an appropriate decision, but also how to generalize this experience to future career problems.

In the 1970s, a line of inquiry emerged from the cognitive sciences that offered a new way of thinking about problem solving and decision making. This paradigm, known as CIP, was initially formulated in the works of Earl Hunt, Allen Newell and Herbert Simon, and Roy Lackman, Janet Lackman, and Earl Butterfield. When applied to career choices, this paradigm, herein referred to as the CIP model, provides a way to describe the fundamental memory structures and thought processes involved in solving career problems and making career decisions. With the CIP model, career counselors can assist clients in becoming better career problem solvers and decision makers.

The CIP model is described in four sections. The first presents key concepts that form its foundation, the second discusses assessing client needs from a CIP perspective, the third describes interventions consistent with this theoretical frame, and the fourth concerns the application of the model in career counseling practice.

### Definitions and Concepts

The following are key definitions in the CIP model to facilitate the understanding and utility of the approach.

*Career problem:* A gap between an existing state of career indecision and a more desirable state of decidedness. The gap creates a state of cognitive dissonance that becomes the primary motivational force driving the problem-solving process. The presence of a gap results in tension or discomfort that individuals seek to eliminate through problem solving and decision making.

*Problem space:* All cognitive and affective components contained in working memory as individuals approach a career problem-solving task. In clients’ lives, the problem space entails the career problem at hand, in addition to all the issues associated with it such as marital and family relationships, financial exigencies, and the emotional states embedded in them.

*Career problem solving:* A complex set of thought processes involved in acknowledging a gap, analyzing its causes, formulating and clarifying alternative courses of actions, and selecting one alternative to reduce the gap. A career problem is solved when a career choice is made from among the alternatives.

*Career decision making:* A process that not only encompasses career choice, but also entails a commitment to and the carrying out of the actions necessary to implement the choice.

*Career development:* The implementation of a series of career decisions that comprise an integrated career path throughout the life span.

### **The Pyramid of Information Processing and the CASVE Cycle**

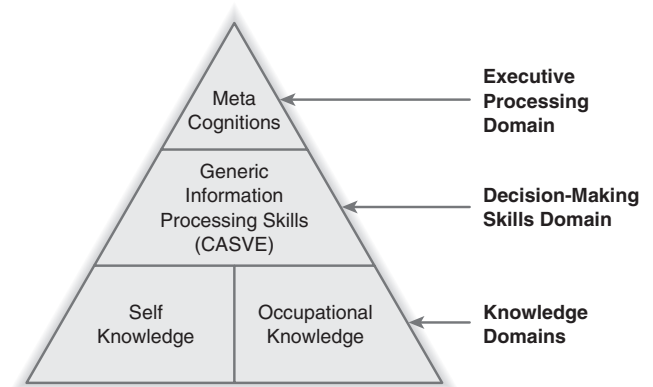

Two fundamental structures comprise the CIP model: the Pyramid of Information Processing and the CASVE Cycle.

#### **The Pyramid of Information Processing**

In order for individuals to become independent and responsible career problem solvers and decision makers, certain information processing capabilities must undergo continual development throughout the life span. These capabilities may be envisioned as forming a pyramid of information processing domains with three hierarchically arranged domains (see Figure 1). The knowledge domain lies at the base, the decision-making skills domain comprises the mid level, while the executive processing domain is at the apex.

*The Knowledge Bases.* Two knowledge domains, self- and occupational knowledge, lie at the base of the pyramid. Self-knowledge includes knowledge about one's interests, abilities, skills, and values based on an ongoing construction of one's life's experiences. Occupational knowledge consists of one's own unique structural representation of the world of work and an understanding of individual occupations in terms of their duties and responsibilities, as well as education and training requirements to attain them.

*The CASVE Cycle.* The midlevel of the Pyramid of Information Processing, referred to as the decision-making

**Figure 1** Pyramid of information processing domains in career decision making

Source: Sampson, J. P., Jr., Peterson, G. W., Lenz, J. G., & Reardon, R. C. (1992). A cognitive approach to career services: Translating theory into practice. *Career Development Quarterly*, 41, 67–72. Used with permission.

skills domain, involves generic information processing skills that combine occupational knowledge and self-knowledge to solve a career problem and to make a decision. A 5-phase recursive information transformation process (see Figure 2), the CASVE Cycle (pronounced “ca-sah-veh”), is used as an overarching heuristic to structure the career counseling process.

1. Communication (C). An individual engages the career problem-solving process by receiving and encoding information that signals that a problem exists. One then queries oneself and the environment to formulate the gap (or discontinuity) that is the problem. This phase also entails getting in touch with all components of the problem space including thoughts, feelings, and related life circumstances.
2. Analysis (A). The causes of the problem are identified and the relationships among problem components are placed in a conceptual framework or mental model.
3. Synthesis (S). Possible courses of action to eliminate the gap are formulated through the creation of possibilities (synthesis elaboration) and then narrowed (synthesis crystallization) to a manageable set of viable alternatives.
4. Valuing (V). Each course of action or alternative is evaluated and prioritized according to its likelihood of success in removing the gap and its probable

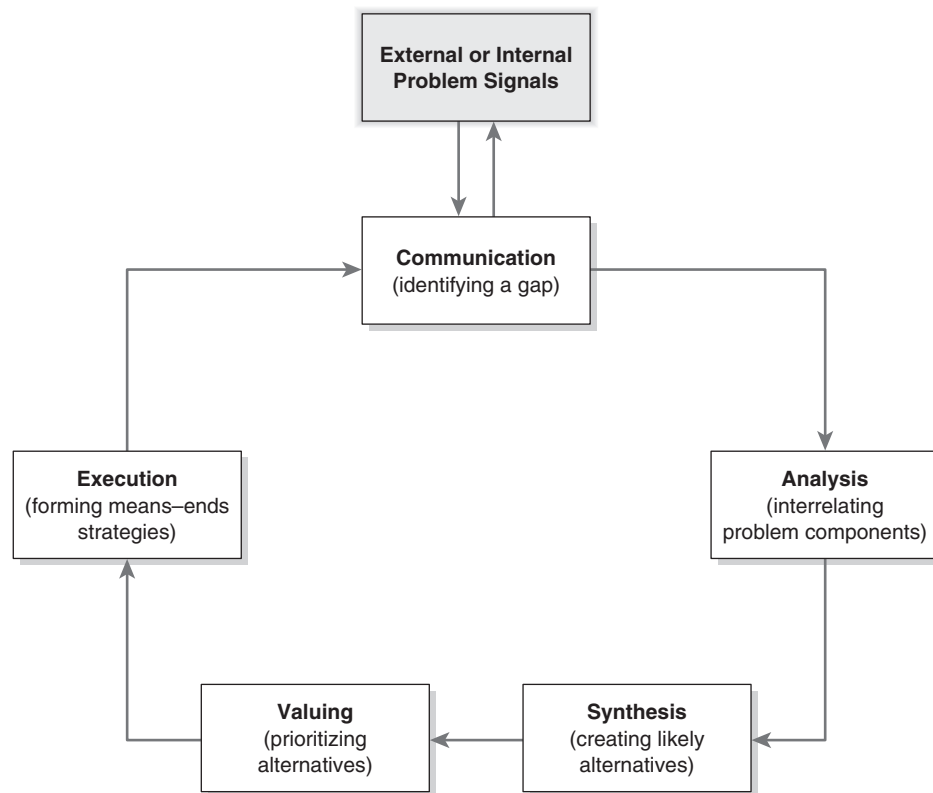

impact on one's self, significant others, cultural group, and society. Through this process a first choice emerges that has the highest prospect of removing the gap. The career problem is now solved.

5. Execution (E). An action plan is formulated to implement the choice, which becomes a goal for the client. A series of milestones are laid out that will lead step-by-step to the attainment of the goal. Thus, a career decision is made when individuals move deliberately toward a goal, such as enrolling in an educational program or taking a job in a chosen occupational field.

Upon executing the plan, there is a return to the Communication phase of the cycle to evaluate whether the decision successfully removed the gap. If so, the individual moves on to solve succeeding problems that arise from the implementation of the

solution. If not, one recycles through the CASVE Cycle with new information about the problem, one's self, and occupations acquired from the initial pass through the CASVE Cycle. Hence, self-knowledge and occupational memory structures evolve with each pass through the cycle.

*The Apex.* The apex of the pyramid, the executive processing domain, contains metacognitive components that guide and regulate the lower-order cognitive functions. This domain can be referred to as thinking about thinking, which entails the ability to view one's self as a career problem solver from a detached perspective. The domain involves metacognitive components that (a) control the selection and sequencing of cognitive strategies to achieve a goal, and (b) monitor the execution of a given problem-solving strategy to determine if a goal has been reached.

**Figure 2** The five stages of the CASVE (Communication, Analysis, Synthesis, Valuing, Execution) Cycle of information processing skills used in career decision making

Source: Sampson, J. P., Jr., Peterson, G. W., Lenz, J. G., & Reardon, R. C. (1992). A cognitive approach to career services: Translating theory into practice. *Career Development Quarterly*, 41, 67–72. Used with permission.

## Assessment of Client Learning Needs

Assessment from the CIP model perspective concerns what clients need to learn to enhance their career problem-solving and decision-making skills so as to effectively address the career problem at hand. The pyramid and the CASVE Cycle serve as heuristics for identifying client learning needs and formulating interventions to remove the gap.

### ***Assessing Readiness for Career Problem Solving and Decision Making***

Not all clients are prepared to immediately engage in the career problem-solving process—they may require intensive personal assistance from a career counselor to manage factors in the problem space that impede learning before they are able to progress through the cycle. Assessing client readiness may be accomplished through integrating information gathered via an intake interview and some type of objective assessment, for example, the Career Thoughts Inventory (CTI). The CTI is a 48-item, self-report measure that assesses the level of client's dysfunctional thinking through three construct scales, Decision-Making Confusion (DMC), External Conflict (EC), and Commitment Anxiety (CA). Scale scores, along with responses to individual items, enable a career counselor, together with the client, to identify discrepancies in the pyramid or blocks in the CASVE Cycle that impede career problem solving and decision making. On the basis of the readiness assessment, clients may be assigned to one of three levels of career service: (1) self-help, (2) brief staff-assisted, and (3) individual case-managed career counseling.

### ***Assessing Career Problem-Solving Skills***

The assessment of problem-solving and decision-making skills entails identifying specific domains in the pyramid that require further development to enable a client to solve the career problem at hand and to make a decision.

*Self-Knowledge.* Assessing self-knowledge is often a confirmatory process in which interest inventories, such as the Self-Directed Search, allow clients to clarify and reaffirm their interests. Computer-assisted career guidance (CACG) systems, card sorts (values, interests, skills), and autobiographical sketches may also be useful.

*Occupational Knowledge.* Occupational knowledge may be assessed through vocational card sorts or by using a card sort as a cognitive mapping task. Through a think-aloud procedure, clients reveal their knowledge about occupations as they sort the cards into like, dislike, or maybe piles. In a cognitive mapping task, clients reveal a schema of the work world by sorting 36 occupational cards into piles of related occupations and then identifying the pile “Most like me.”

*Decision-Making Skills.* The CTI may be used to identify specific CASVE Cycle phases in which clients experience blocks in the career problem-solving process brought about by dysfunctional career thoughts. The DMC scale reveals dysfunction in the communication, analysis, and synthesis phases that entail deriving career alternatives; the EC phase addresses the valuing phase in which clients weigh the importance of their views in relation to views of significant others; and the CA scale alludes to reaching closure in identifying a first choice, as well as the transition from arriving at a career problem solution in the valuing phase to a commitment to action in the execution phase.

*Executive Processing.* Dysfunctional thoughts in this domain may also be assessed through responses to individual items on the Executive Processing content scale of the CTI. In addition, during the client interview a career counselor may listen carefully for instances of negative self-talk, ineffective cognitive strategies, and lack of thought or behavioral control in staying focused on the problem-solving task at hand.

The outcome of the assessment process is the development of an individualized learning plan (ILP) consisting of counseling goals to address the identified deficiencies and blocks that impede problem solving and decision making.

## **Interventions to Help Clients Acquire Career Problem-Solving and Decision-Making Skills**

The pyramid and CASVE Cycle are instrumental in developing interventions that facilitate the acquisition of required self-knowledge, occupational knowledge, and career problem-solving and decision-making skills identified in the assessment process.

### ***Acquiring Self-Knowledge***

The acquisition or clarification of self-knowledge may be accomplished through the use of interest inventories, values inventories, and ability and skills assessments that typically affirm and clarify the elements of the self-knowledge domain. Autobiographies may also be helpful in describing and organizing life experiences that bear on the career problem at hand.

### ***Acquiring Occupational Knowledge***

In career counseling, clients engage in the processes of schema specialization in which they are able to make finer discriminations among occupations, as well as schema generalization in which they form more extensive networks of connections among extant occupational knowledge structures. When career counseling takes place within comprehensive career centers, the acquisition of occupational knowledge may be facilitated through the use of a variety of media, including occupational briefs, vocational biographies, reference books, special topics books, videos, interactive media, and Internet Web sites. Reality testing through job shadowing or interviews with job incumbents allows clients to experience occupations even more directly.

### ***Acquiring Career Problem-Solving and Decision-Making Skills***

The concept of the Pyramid of Information Processing Domains is presented directly to clients in a handout called "What's Involved in Career Choice." The concepts of communication, analysis, synthesis, valuing, and execution and the cyclical relationship among these concepts are learned via a handout depicting the CASVE Cycle, which uses simple statements to describe each phase. Then, through subsequent review of ILP activities and feedback from a counselor, clients begin to accommodate and assimilate the CIP model into their own decision-making style. At the termination of counseling, the counselor reviews the decision-making process undertaken and demonstrates how the CIP model can be used in future career problem situations.

### ***Acquiring Metacognitive Skills in the Executive Processing Domain***

When dysfunctional or negative thoughts are identified in the assessment process, clients learn how to

change their dysfunctional or negative career thoughts using the ICAA algorithm (Identify, Challenge, Alter, and Act). *The CTI Workbook* takes clients step-by-step through a cognitive restructuring process. Clients also learn how to self-monitor their progress through the CASVE Cycle.

## **Implementing the CIP Model in Career Counseling**

### ***The Seven-Step Sequence***

A seven-step career service delivery sequence is used as a heuristic for implementing the CIP model in career counseling.

1. *Initial interview:* The career counselor gathers qualitative self-report information about the nature of a client's presenting career problem.
2. *Preliminary readiness assessment:* An individual's readiness for career counseling is assessed through administering the CTI. The findings are reviewed and discussed with the client.
3. *Define the problem and analyze the causes:* The counselor and the client come to a mutual understanding or common mental model of the career problem and related issues. The specific causes of the problem lie in the deficiencies within the respective domains of the pyramid or blocks that impede progress through the CASVE Cycle.
4. *Formulate goals:* The counselor and client together formulate a set of attainable goals, stated in behavioral terms, to remove the gap.
5. *Develop an ILP:* For each goal, the counselor and client develop learning activities to attain the goal, resources used in the activities, estimated time to carry out the activities, and the priority for each activity.
6. *Execute ILP:* Clients carry out the ILP while the counselor monitors the attainment of the respective goals and assists the client when required.
7. *Summative review and generalization:* The client and counselor review the process used to solve the problem and make the decision at hand and evaluate its effectiveness. They also explore how the CIP model might be applied to future career problems or even to life problems in general.

### **Implications for Best Practices in Career Service Delivery**

The CIP model advances the state-of-the-science in career counseling by providing a theory base for introducing a value-added dimension, that is, using the problem at hand as a means for furthering the acquisition of career problem-solving and decision-making skills. Moreover, focusing specifically on what clients are required to learn to improve their career problem-solving skills, counselors can look beyond the traditional one-on-one counseling relationship and creatively develop facilitative learning environments. Finally, assessing readiness for career problem solving enables counselors to match career service delivery resources to the depth and scope of the presenting problem, thereby fostering greater efficiency in the administration of career services.

The CIP model serves as a heuristic to enable individuals to systematically think through a career problem. By applying the model to solve a presenting problem, clients become better career problem solvers and decision makers, which in turn, can lead to satisfying, meaningful, and productive careers.

## **COLLEGE STUDENT EXPERIENCES QUESTIONNAIRE**

---

The College Student Experiences Questionnaire (CSEQ) is a versatile tool that assesses the quality of effort college students expend in using resources and opportunities provided by an institution for their learning and development. Quality of effort is a key dimension for understanding student satisfaction and persistence and for understanding the effects of attending college. The more students engage in educationally purposeful activities, especially those recognized as good practice in education, the more they benefit in meaningful ways in their learning and development.

The CSEQ asks students to report the frequency with which they participate in common college activities, their perceptions of the college environment, and their estimates of individual gains related to areas of their personal and social development. The college activities questions explore such topics as how often students make contributions in classes, how often they receive prompt faculty feedback, and how often they interact in meaningful ways with peers in different

contexts. The college environment questions ask students about their perceptions of the psychological climate for learning that exists on the campus. For example, do they view their campus as supportive of their academic efforts? The estimate of gains items ask students to reflect on their entire college experience and to estimate how much progress they feel they have made in areas of personal and practical development common to the college experience. The gains items represent holistic development, assessing such wide-ranging outcomes as acquiring relevant career information, writing clearly and effectively, understanding self and others, and gaining the ability to think analytically and critically.

Institutions use CSEQ data to determine program effectiveness, measure learning outcomes, assess academic year initiatives, and expand efforts of academic affairs and student affairs divisions, among others. With more than 150 items, the CSEQ provides institutions with valuable information about student experiences. Furthermore, student respondents may also benefit from the reflection and self-evaluation exercise associated with completing the survey. Many students say filling out the questionnaire prompts them to recall the range of activities in which they participated during the year and the progress they made toward important goals.

In addition to the CSEQ instrument, the CSEQ Research Program offers the College Student Expectations Questionnaire (CSXQ), which assesses new student goals and motivations. New students arrive with expectations about how and with whom they will spend their time in college. These expectations provide clues about how they will interact with peers and faculty members, which are behaviors that directly affect achievement and satisfaction with college. When paired together, the CSEQ and CSXQ instruments allow institutions to assess the degree to which student and institutional expectations are met.

## COMPUTER-ASSISTED CAREER COUNSELING

---

Computer-assisted career counseling is the use of computers in educational and career guidance. When faced with the prospect of having to make an important educational or career decision, many individuals look for career or educational information and professional guidance. Individuals making educational decisions might access college brochures and catalogs or might request application and financial aid materials. Alternatively, individuals considering a possible career path might access information about the tasks involved in a job or might research the employment outlook for a particular occupation. Furthermore, some individuals seek the guidance of trained career counselors and psychologists as they grapple with making their decision. More and more, individuals are turning to their computers and the Internet for both information and guidance. A recent report, for example, suggests that almost half of all U.S. Internet users have turned to the Web when making important educational and career decisions.

The use of computers in educational and career guidance has a long history. In the 1960s the U.S. Department of Labor funded a project to develop a computer program that could provide users with up-to-date data on employment and educational

opportunities. Early computer-assisted career guidance (CACG) programs were available in the 1970s and included automated career assessments; searchable databases of colleges, majors, and occupations; and guidance-related information to promote action planning and decision making. The widespread proliferation and availability of Internet technologies has radically changed the landscape of computer-assisted career counseling. Today, computer-assisted career counseling takes four primary forms: computerized career assessment, electronic sources of career and educational information, comprehensive CACG systems, and online career counseling.

### Computerized Career Assessment

In an effort to help clients understand their educational and career interests, skills, and values, career counselors and psychologists will often administer one or more career assessment inventories. Results from these inventories can be used to help clients identify career paths, confirm existing choices, or narrow the number of career alternatives considered. Several benefits can be realized when administering career assessment via computer. Traditional paper and pencil inventories require that all items be administered in a fixed order. Computers can administer items dynamically based on individuals' responses (referred to as computer adaptive testing or CAT). Computers can also be programmed to provide a reliable interpretation of an individual's inventory results. When linked with other computer career assessment results, clients can be provided with interpretations and recommendations based on the integrated findings from multiple inventories. Finally, assessment interpretations themselves may be dynamic and interactive, requiring input from users or linking results and interpretations to sources of educational and occupational information.

Today, most computerized career assessment inventories are delivered via the Internet. Professionals and consumers should exercise caution when selecting online career inventories as many Internet-delivered inventories are of questionable origin. Inventories distributed by reputable testing companies or independently developed inventories that are supported by published research are preferred. Professionals should review the psychometric properties of any instrument prior to using it in practice. Three of the most widely administered online career interest inventories are the Strong Interest Inventory, the Self-Directed Search, and the Kuder Interest Inventory and Career Planning

System. Other widely administered interest inventories include the UNIACT and the Occupational Information Network (O\*NET) Interest Profiler, which are embedded with comprehensive computer guidance systems. In addition to interest inventories, work values and skill confidence inventories can also be found online.

### Online Source of Education and Career Information

The use of computers to provide education and career information was first realized by the Department of Labor in the 1960s. Today, universities, private business, government agencies, and private citizens are free to publish information on the Internet. When compared to traditional printing methods, the Internet offers several benefits. Information can be updated on a regular basis and published almost immediately. Electronically delivered material can be quickly indexed and cross-referenced and text-based materials can be easily searched by end users. When the information is maintained in a relational database, it can be searched using preprogrammed compound searches. For example, a user can request a listing of all occupations that have starting salaries averaging greater than \$50,000, require a bachelor's degree or less, provide opportunities to supervise others, and are projected to be in high demand in coming years.

Several excellent college search sites are currently available free of charge. Both ACT, Inc., and the College Board provide an interface that permits searching for colleges by geographic location, admissions selectivity, tuition costs, and a host of other criteria. Resulting lists are linked directly to the college's homepage.

The most comprehensive source of free occupational information is the U.S. Department of Labor's O\*NET. The O\*NET is a comprehensive system of products, databases, and services designed to organize, describe, distribute, and collect information on occupations and the workforce. The O\*NET database is in the public domain and can thus be freely downloaded and distributed. The O\*NET online permits searching of the O\*NET database using several criteria (e.g., interests, values, job family, employment growth). Several CACG systems make use of the O\*NET database in delivering occupational information to their subscribers. The Department of Labor continues to maintain the *Occupational Outlook Handbook*, which served for many years as the primary governmental source of occupational information.

While the Internet has revolutionized the way education and career information is distributed, it has also caused some concern among career counseling professionals. Of particular concern is the overall quality and accuracy of career and educational information provided on the Web. Several professional organizations have established guidelines and standards for providing online career information. For example, the National Career Development Association has established guidelines that can be used by practitioners who wish to use the Internet to provide career information and planning services. Similarly, the Association of Computer-Based Systems for Career Information has established a set of standards to help guide career guidance program developers in building the highest quality career information services. Counselors and career professionals are urged to familiarize themselves with guidelines for evaluating the accuracy and currency of Internet delivered career and educational information.

The availability of accurate educational and career information may be more important than was previously thought. Results from a recent meta-analysis suggest that some elements of career counseling are more important than others. These authors suggest that providing clients with opportunities to access information about the world of work might be among the most potent predictors of positive outcomes among clients who are making initial career decisions.

### **Computer-Assisted Career Guidance Systems**

CACG system is a term used to describe a computer application that combines career assessment, career information, and career guidance into one integrated system. CACG systems have been available since the 1970s and have evolved to take advantage of new computer technologies (e.g., personal computer, Internet). A growing number of CACG systems are available and most today are sold as subscription services delivered through the Internet.

CACG systems are unique in that they combine the advantages of providing online assessment; searchable databases of schools, college majors, and occupations; and other guidance and exploration experiences with the additional advantages that come from combining these features into one integrated system. In these systems, users typically receive their career interest assessment results in a format that permits

immediate exploration of career alternatives. In the DISCOVER program, for example, individuals' interests are compared to the characteristics of occupational environments and users are provided with possible career areas to explore (ordered from highest to lowest) based on their interests. Selecting a career area provides the individual with a list of occupations within that group and users can subsequently research occupational titles to learn about job tasks, educational requirements, employment outlook, or salary. Similar crosswalks are often created between values and skills assessments and occupational characteristics. Furthermore, CACG systems often provide information related to college majors and postsecondary schools in relational databases. These elements may also be searched using standard compound search routines.

CACG systems offer several other advantages. Because CACG systems are so costly to produce and distribute, they are generally produced by established for-profit and not-for-profit companies. As such, one can assume a level of quality assurance and professional review that may not be present with some stand-alone Web sites. Many CACG systems also permit some level of site customization. For example, site administrators may customize log-in banners, create unique surveys that appear within the program, or construct site specific data elements (e.g., high school coursework planner that shows site specific course names and numbers). Several CACG systems are currently in widespread use including DISCOVER, SIGI PLUS, and Choices.

There is a growing body of research suggesting that CACG systems are effective at promoting career development and decision making. Several recent meta-analyses show that CACG is effective, though effect sizes appear to be larger when computer-assisted guidance is combined with counselor-assisted guidance. Counselors or psychologists wishing to use CACG systems in their practice are urged to consider ways in which CACG systems can supplement their one-on-one or group-based career interventions.

### **Online Career Counseling**

The computer and the Internet are expanding the ways in which clients and counselors are engaging in career counseling. The expansion of career counseling to the Internet is not surprising; counselors have a history of incorporating technology and distance communication

(e.g., telephone) into their practice. New modes of service delivery include e-mail, online chat, videoconferencing, voice over IP (Internet phone), and Weblogs. While there are endless possibilities for the provision of career counseling services through distance communication technologies, many risks and challenges accompany these new delivery platforms.

Online career counseling is particularly exciting as it may create the opportunity for geographically isolated or homebound individuals (due to mental illness or physical disability) to access services that would otherwise not be available. Individuals who traditionally have not sought counseling, those who are more comfortable with the anonymity provided by the Internet, and those underserved or underrepresented populations may also be more likely to seek services. Online career counseling also presents substantial challenges and potential risks. There are a number of untested legal issues that arise in online career counseling, including practicing across state lines and the coverage of malpractice insurance. It is also possible that not all career concerns are appropriate for online counseling, and most graduate training programs are not preparing counselors to provide online services. Finally, access to technology, particularly high-speed Internet, will limit the ability of many to access career counseling services.

One important distinction in online career counseling is the difference between asynchronous and synchronous communication. E-mail and blogs represent asynchronous communications, where two individuals are not required to be present or online at the same time to communicate. Exchanges through e-mail or blogs allow individuals to compose, edit, review, and respond to messages at their convenience and to create great flexibility in the speed, timing, and frequency of response. Another potential benefit of this communication modality is that clients may derive therapeutic benefit through the act of writing itself. Challenges include maintaining the client's confidentiality, the loss of nonverbal cues, and counselors clearly articulating the timing and frequency of their responses to clients.

Synchronous communication is characterized by real time interaction between client and counselor and includes online chat, videoconferencing, and voice over IP. Online chat is accomplished through messaging systems or Web pages and allows clients and counselors to communicate in real time through typing. Online chat allows the counselor to experience the

timing of responses as well as immediately respond to clients' content. Ethical concerns with this mode of interaction include the possibility of losing tone and emphases of verbal communication, misunderstandings due to not recognizing cultural differences, the security and storage of transcripts of sessions, and potential technology failure. Videoconferencing, which most closely approximates traditional face-to-face counseling, builds upon many of the above benefits and increases the likelihood that verbal and vocal cues will be conveyed during interaction. Access to a broadband Internet connection, expensive video equipment, as well as lighting difficulties and restricted field of vision are all limitations to career counseling through online videoconferencing. Finally, voice over IP is essentially the equivalent of telephone counseling, but may be done at much lower cost and allows participants to simultaneously view content such as assessment results or blog postings on the Internet.

The preliminary research examining the effectiveness and equivalency of online counseling is positive and suggests that e-mail, chat, and videoconferencing are appropriate modalities of career counseling services for some clients. For example, research has compared counseling offered through videoconferencing, speakerphone, or traditional face-to-face counseling and found equivalent and positive outcomes for clients in all three conditions. Findings such as this are encouraging first steps, while much more research remains to clearly identify the problems, clients, career interventions, and communication modalities that are appropriate for online career counseling.

### Considerations for Counseling Professionals

Technological advances during the past 25 years have shaped the work of vocational psychologists and career counselors. Online counseling, Internet assessment, and comprehensive CACG programs are now common aspects of many professionals practice. Professionals are encouraged to embrace these and emerging technologies in their practice but to do so in a way that ensures that technology is applied in helpful and responsible ways.

## CONSTRUCTIVIST CAREER COUNSELING

---

The theory of constructivism has roots in philosophy, science, psychology, sociology, and anthropology. The core of the theory involves the idea that reality is relative rather than absolute and that people actively create reality by the way in which they experience and

interpret events. As an example, take the idea of stealing another person's money. While some may say that stealing is always wrong and is never justified, others may say that certain circumstances may make stealing understandable. The story of Robin Hood certainly appeals to that notion that what is right and what is wrong is a matter of perspective.

Like other theory-based practices, career counseling has evolved to account for this idea that reality is relative and is created through experience and interpretation of that experience. Although models of practice developing from this new perspective are varied, the theoretical underpinnings share common characteristics that separate them from more traditional mainstays in vocational psychology. Traditional vocational counseling theory developed in an age of modernist ideals and emphasized objectivity, neutrality, reductionism, quantification, and measurement. Models and interventions based on these theoretical underpinnings focused on the person, represented by a set of stable, measurable traits and the world of work, represented by definable characteristics of established occupations and stable career paths.

### Paradigm Shift for Career Theory

Constructivist career theory represents a paradigm shift from these modernist principles toward postmodern ideology. Postmodernists believe that multiple realities exist simultaneously rather than the presumption of one measurable truth. Reality and truth are matters of individual perception and are constructed by individuals as a way of organizing complex information about themselves and the world. Human behavior, then, can be understood only in the context in which it occurs. People use personal constructs or theories they have created about life to organize and account for their experiences and associate meaning through decisions and actions. Individuals use these constructs to evaluate themselves and others, make judgments about the world, and predict the future. As active agents in their lives, people refine their constructs over time based on their life experiences and their reactions to and processing of those experiences.

### Implications for Career Counseling

This core conceptual change has strong implications for the theory and practice of career counseling. Operating under the new assumption that individuals

actively participate in the creation of their own reality, career is viewed as an individual construct. The meaning people attach to career is reflective of their social, psychological, historical, and cultural relationships and experiences. Traditional vocational psychology with its emphasis on stable personal traits and measurable characteristics of occupations becomes less relevant within the context of changing realities.

Specifically, constructivist career counseling requires a paradigm shift from examining behavioral traits to looking at action, meaning, and life themes. In addition, it requires a shift from assessment of causation to more reflective processing. It also encourages counselors and clients to see the self as progressively constructed or a work in progress rather than predetermined. Instead of quantifying traits, career counseling involves exploration of how clients construct meaning from present actions and past experiences. As a construct itself, career accounts for connectedness between actions, accommodates roles and relationships in a variety of settings, reflects purposeful efforts toward planning and goal setting, as well as reflecting internal states such as emotion, arousal, passion, and personality. An individual's construct of career is an overarching framework for understanding and organizing complex patterns of intentional actions over the lifespan. The career development process therefore involves individuals intentionally engaged in acquiring meaning within the constructs of their lives. Life and career transitions, whether purposeful or in reaction to unexpected change, stimulate changes in personal constructs.

R. Vance Peavy was among the first to outline, articulate, and advocate the shift to constructivist career counseling. In a time when clients' lives and careers are increasingly ambiguous and uncertain, Peavy suggested that self-construction and life planning replace simple focus on career choice. He emphasized that clients should move away from the idea that there is one right answer, but rather that some answers are better than others. As individuals create realities through the interpretations they make and the actions they take, they must take responsibility for their own thinking and actions.

Peavy also focused a great deal of time and attention on the relational nature of career construction. People use language to make meaning out of their daily lives, especially in interactions with others and with aspects of the surrounding world. The counseling process is one of collaboration with the counselor bringing expertise on the career development process

and the client bringing self-expertise. The goal then becomes pattern recognition and mindfulness toward the creation of new constructs, receptivity to new information, and awareness of multiple perspectives.

## The Practice of Career Counseling

The process of constructing possible realities involves action. As individuals define themselves and their environments they are actively participating in the creation of new realities and personal stories. The use of language and dialogue (internal or with others) is critical to the creation of meaning and knowledge. In career counseling, individuals' career constructs, stories, and personal mythology are explored and a new reality is created through dialogue between counselor and client. This process invites nonlinear conversations wherein new stories are written, existing stories are revised, and possible selves are explored. Unlike some traditional models that compared individuals to a set of norm-referenced traits, constructivist career counseling respects sociopolitical and cultural contexts in which clients live. This makes constructivist counseling especially useful with diverse client populations and a vast array of individual differences.

A number of models have emerged within this theoretical perspective including narrative career counseling, action theory, the self-construction model, and relational theory. Within these models, new vocational interventions designed to complement the counseling experience are being developed. Although diverse in nature, design, and intended outcome, these interventions generally encourage reflection on activity through storytelling, assessment of themes, journaling, concept mapping, assessment of strengths and accomplishments, and metaphor. With the focus on dialogue and relational empowerment, constructivist career counseling is also being used increasingly in group settings. In addition, more traditional interventions are being reviewed, revised, and reinterpreted for understanding within a constructivist point of view.

## CONTRACT WORK

---

Rather than continuing as a salaried employee at a college or agency position, some counselors choose to establish a private career counseling practice and engage in contract or consulting work. Contract work can be very fulfilling, financially rewarding, and provide tremendous freedom to develop and experiment

with numerous interventions while focusing on preferred niches that match one's highest passions. Success ultimately depends on discipline, setting priorities, and having a measured sense of risk, adventure, and entrepreneurship.

### Factors Associated With Choosing Contract Work

A main motivation for many private practitioners that probably influences them to engage in contract work is the opportunity and freedom to concentrate primarily on individual counseling activities with clients and engage in those activities directly related to preferred interests. Counselors choose to be counselors because they enjoy the counseling relationship and believe that this one-on-one interaction can effect change and assist clients with their concerns. Individual counseling does work, and many counselors prefer this one-on-one relationship for good reasons.

Research findings by T. L. Sexton, S. C. Whiston, J. C. Bleuer, and G. R. Walz indicate the primary factors that effect outcome in career counseling are the type of treatment modality and the duration of time spent counseling and cite individual counseling as the most effective treatment modality. Further research by A. R. Spokane describes individual career counseling as the most efficient career intervention in terms of amount of gain per hour of effort. This one-on-one approach is viewed by J. Rayman as a superior career intervention based on a therapeutic alliance that should be available in comprehensive career centers. Ironically, this presents a daunting challenge to those counselors who prefer the infrastructure of a college or agency setting to consider alternative methods to sufficiently meet client demand. Several factors affect career services providers in college and agency settings and deter them from delivering their preferred mode of individual counseling.

### Time Constraints

Time on task is a major concern. The reality is that most career services providers, especially in college settings, are very busy with many noncounseling job responsibilities and unable to sufficiently provide the comprehensive individual career counseling required to meet the needs of their clients. Department meetings, administrative responsibilities such as report writing and budget preparation, orientation and

registration activities, academic advising, classroom presentations, and teaching career exploration courses take time and effort, and can detract from concentrated in-depth individual counseling interventions. Even in those college and agency settings where more time might be available for individual counseling, very small percentages of counselors are able to provide the 9 to 10 sessions normally required for effective career interventions.

### ***Client Demand***

Another factor that deters counselors from providing individual counseling relates to the large client demand evident at most postsecondary institutions and agency settings. Secondary school students' needs for career guidance remain largely unmet, and they bring their unmet needs to the college environment, contributing to the estimated half of all undergraduates in colleges and universities who need some form of career assistance. As calls for accountability increase from multiple stakeholders and more colleges and agencies utilize important needs assessment and outcomes research, the evidence of unmet needs will be further documented resulting in more pressure on staff to produce better results.

### ***Insufficient Staff***

Finally, there are simply not sufficient numbers of counselors to provide comprehensive individual-based services within the infrastructure of most education and agency settings in the United States or in similar settings internationally. These settings are not structurally organized up to provide comprehensive individual career counseling to large numbers of clients. Few counselors are hired, and yet these few counselors are expected to provide appropriate services to meet the career counseling needs of many clients. Thus, counselor-client ratios are very high leaving a limited pool of stressed-out counselors to attempt to accomplish the important work that needs to be done.

Colleges and agencies need to think creatively and wisely as they develop ways to cost-effectively meet the needs of the many clients who frequent their physical structures. Unfortunately, individual counseling, career exploration and planning courses, workshops, the use of computer-assisted career guidance systems (CACGS), and other activities cannot

effectively reach the multitudes. In many college and agency settings, the prevailing treatment modality remains career counseling by appointment, a familiar, comfortable, and proven intervention, yet clients' needs are not sufficiently met. What is needed is the application of systematic career guidance (SCG) with small structured groups that at least begins to cost-effectively deal with this demand. Sadly, the majority of college students will probably experience their college years without spending sufficient time and energy in what E. A. Colozzi describes as committed career exploration activities. Their unmet needs will be carried forth into their first time employment experiences from which they will eventually change jobs 7 to 10 times in two or three unrelated careers during their work history.

### **A Catalyst for Inspiring Contract Work**

These factors will result in a great need for private practice counselors to assist with the growing demand for career/life counseling in an ever-changing global economy. This situation presents a very positive employment opportunity for school, college, and agency counselors who might be considering establishing a private practice because they prefer not to deal with the many other activities that often are an integral part of the job responsibilities at most educational and agency settings. Thus, the stage is set for those career services providers who choose to shift from being salaried employees to being consultants who provide contract work and earn income directly from one or several sources including individual paying clients and corporate or agency clients.

Choosing to become an entrepreneur is an exciting venture that requires a business vision, planning, marketing, constant evaluation, support from others such as family, friends or mentors, and a sense of adventure, even calculated risk. Research indicates entrepreneurs establish an average of 500,000 new businesses monthly in the United States with small businesses (independent businesses having fewer than 500 employees) representing 99.7% of all employer firms. Small businesses are the largest growing segment of the U.S. economy, responsible for more than two thirds of new jobs, and the majority of small businesses are entrepreneurs without employees as reported by S. Gelardin in a new monograph that focuses on starting and growing a new business.

## **Contract Work Opportunities**

There are several creative ways to provide services to potential individual and corporate clients. One involves direct services to clients needing individual counseling and career/life coaching. Another involves providing services to an agency college or corporate client that might include onsite individual counseling and small and large group workshops for employees. Some corporate clients may simply have a need for the development of materials that better serve their target niche of clients and customers, and this type of contract work would preclude directly seeing individual clients and doing group workshops. Distance counseling via telephone or using the Internet with blogs, Podcasting, and video are other ways to meet client needs. New technologies are expanding the many and varied exciting ways to provide career counseling in a global community that presents a thriving economy for the contract career counseling profession.

## **Establishing the Office and Targeting the Market**

The establishment of a private practice where clients come to an office or home office and obtain services directly from a counselor is an obvious choice. Less overhead and other costs result in more income. Penetrating the right market increases income. The focus could be on comprehensive individual career counseling and perhaps small group work. Selecting a niche such as adults 30 to 50 years of age, new entrants to the labor market who have primarily been homemakers, or focusing on young adults are just a few of many possibilities. The key is to start from one's strengths and passions. Concentrate on abilities, talents, and interests to identify a target niche, and then develop a marketing plan to penetrate that selected market. The focused approach of niche marketing needs to be carefully balanced with creating sufficient content or product diversification to ensure income flow if one's niche market experiences an economic hiccup! It is difficult and unwise to establish a private practice immediately following graduate school. One requires experience to be successful, and experience is best gained from working in an educational or agency setting where many clients or customers seek career counseling. If one dreams of doing contract work as a private practitioner, consider any work at an appropriate college or agency setting as

simply a paid internship—a bridge job that progresses one forward and teaches new skill sets.

## **Being a Successful Businessperson and Counselor**

There are numerous rewards associated with establishing oneself as a contract worker and private practitioner, including a great amount of freedom to do the specific types of work and projects that are fulfilling. One key to success is the clarity one has concerning the role division between businessperson and counselor. It is important, even critical as one develops a business plan, to be aware of the many business tasks that are necessary to successfully provide contract work as a private practitioner and consultant.

If the assumption is that to be successful in private practice, one must see oneself equally as a businessperson and a career counselor, a 50/50 even split, not a businessperson first and then a career counselor, the contract work may quickly end due to unrealistic priorities. It is imperative to always see oneself and act as a businessperson first—at least 51%. This requires organizing time and tasks in the context of business goals first and then serving customers—clients with integrity in ways that meet their needs. This approach will allow a reasonable profit so the contract work can continue to support one's business as a private practitioner, doing the counseling and consulting one thoroughly enjoys. The other option is to work for a college or agency setting primarily as a career counselor and not have to deal with the business aspects of running a private practice and doing contract work.

## **Future Directions**

Small businesses have been around from the earliest time a person started to offer a service or provide a product for the community. They are always growing and changing, and will be offering many exciting opportunities for future generations. In the career counseling field many people are discovering opportunities to offer their services for a fee. There are human and written resources that will support this effort including advice, mentoring, and basic tips that facilitate starting and growing a successful business in the career counseling profession. Much of this information is available through the National Career Development Association (NCDA), and their Web site

offers excellent free career information and a variety of resources. Another organization that focuses on school youth is JA Worldwide (Junior Achievement), and their Web site offers very user-friendly resources for youth, parents, and educators, including links to arrange having a JA volunteer visit a school and present several workshops for students on many topics such as entrepreneurship, career exploration, and the global economy.

## CRITES, JOHN O. (1928–2007)

---

John O. Crites completed the A.B. degree in history from Princeton University in 1950 (magna cum laude) and the Ph.D. degree in Counseling Psychology from

Columbia University in 1957. He made a number of significant professional contributions at the University of Iowa where he started the Counseling Psychology Program in 1958. He was the Head of the Counseling Psychology Program and the Director of the University Counseling Service until he moved to the University of Maryland in 1971 as a Professor of Psychology. In 1981, he was hired as a research professor at Kent State University; in 1985, he became Director of the Counseling Psychology Program at Northwestern University; and he became a Visiting Professor of Psychology at the University of Denver as he moved into retirement.

Over the years Crites was a very productive professional person and a leader in the field of counseling and vocational psychology. He authored or coauthored four textbooks, 15 chapters, seven monographs, and 35 published manuscripts. Two books (*Appraising Vocational Fitness*, revised with Donald Super, and *Vocational Psychology*) were early and very original contributions to integrating theory, data, and practice in the field of vocational psychology and career development. His book *Career Counseling: Models, Methods, and Materials* was one of the first attempts to present theories of career counseling within a data-based perspective. He also served on a number of editorial boards during his long and distinguished career.

Honors and awards include the American Board of Professional Psychology Diplomate in Counseling Psychology, the American Personnel and Guidance Association Research Award in 1966, the Merit Award from the National Vocational Guidance Association in 1973, the Recognition Award from the Association of Measurement and Evaluation and Guidance in 1973, the Eminent Career Award from the National Vocational Guidance Association in 1984, and the Walter F. Storey Award from the American Society for Training and Development in 1985. He was a Fellow of the Division of Counseling Psychology of the American Psychological Association and a Fellow of the American Association for the Advancement of Science. In 1972 he served as the President of the Division of Counseling Psychology of the American Psychological Association.

His most notable contributions were twofold. He wrote the first major text defining the field of Vocational Psychology (1969) that has had a long-term influence on research and training in counseling psychology. His operationalization of and theorizing about the vocational development view of careers set

the stage for much of the work that followed. In particular, the Vocational Development Attitude Scale, the Decision-Making Competency Scales, and the Career Maturity Inventory were the forerunners of many current scales and inventories.

Crites had a distinguished career of original research, scholarship, and application as well as of outstanding service and leadership. He was clearly one of the outstanding contemporary counseling psychologists of our time. His theoretical concepts, insights, and empirical research have had a significant influence on the field of counseling and vocational psychology. Crites passed away in March 2007.

## **DAWIS, RENÉ VILLANUEVA (1928– )**

---

René Villanueva Dawis continues to be a major contributor to counseling psychology and to the psychology of individual differences. Born in the Philippines in 1928 into the family of a professor of agronomy, Dawis received his B.A. (cum laude) from the University of the Philippines in 1951 and spent 2 years as an instructor in psychology at that same university. He then entered the graduate program in psychology at the University of Minnesota, where he completed his master's degree in 1955 and his Ph.D. in 1956. Dawis returned to the University of the Philippines for a year as an assistant professor, but his graduate adviser—the legendary Donald G. Paterson—recruited him as the research director for a new research project at the University of Minnesota under then Associate Professor Lloyd H. Lofquist and his colleague George W. England.

The goal of the 2-year project, funded by the then U.S. Office of Vocational Rehabilitation (OVR), was to evaluate the effectiveness of the vocational rehabilitation process. The project was so successful that OVR then funded what was to become the Work Adjustment Project with Dawis as its first research director. A major product of that project, which was funded for almost 15 years, was articulation of the theory of work adjustment, which has guided much of Dawis's research in vocational psychology since that time. With Dawis as its research director for 5 years and then coprincipal investigator with his lifetime colleague Lloyd H. Lofquist for the remainder of the project's funded years, the Work Adjustment Project was

the training ground for many Minnesota psychology graduate students who continue with new generations of students to make important contributions to vocational psychology.

The Work Adjustment Project under Dawis's guidance was the source of the Minnesota Importance Questionnaire and the Occupational Reinforcer Patterns, both of which The Work Adjustment Project uses to assist vocational counselors in identifying occupational choices for counselees; the project also uses, among other instruments and materials useful in vocational counseling and counseling research, the world's most popular measure of job satisfaction, the Minnesota Satisfaction Questionnaire. The theory of work adjustment, originally articulated in a 1964 monograph, was revised in 1969 and has been continually expanded and updated since in two books with Lofquist and in numerous journal articles, monographs, and book chapters even after Dawis's retirement from the Psychology Department at the University of Minnesota in 1997.

In his highly productive and continuing career, Dawis has published 63 journal articles, 51 research monographs and technical manuals, six books, and 30 book chapters. His research garnered him awards and recognition from organizations such as the American Personnel and Guidance Association, the American Rehabilitation Association, and the American Psychological Association. In addition, he was the graduate adviser to 78 students who completed Ph.D.s in psychology. Like many University of Minnesota psychology faculty, Dawis was not content to just teach and do research, but he also served as a consultant to over 50 organizations in government, industry, and the

private sector, sharing his expertise for the good of society.

## DECISION MAKING

---

Decision making refers to the process by which an individual comes to choose between two (or more) alternative courses of action. For career decisions, this process might lead to the choice of a major, a more general occupational direction, or a particular job. Decision making might also lead individuals to explore some career directions and not others or to abandon choices previously made. Regardless of the specific context, career decision making reflects the process through which individuals take in, weigh, and make judgments about themselves in relation to the world of work.

Decision making has been studied both as a process and as a source of individual variation. In turn, the process of decision making has been framed in both descriptive and prescriptive ways, and models of individual variation have been advanced that reflect

both individual styles and the context of the decision-making environment. Each of these major perspectives is described here.

### Decision-Making Process

Tracing back to the earliest study of human cognition, theorists have sought to describe how it is that people arrive at a single course of action as well as how decisions should be made optimally.

### *Descriptive Models of Decision Making*

Descriptive models of decision making are those that simply describe or detail the steps involved in the process of making a decision without advocating for how the process should proceed. In one of the first efforts to describe career decision making, David V. Tiedeman provided a comprehensive model that portrayed the process as a sequence of stages leading up to and following the point of choice. Prior to choice is a stage of anticipation in which individuals explore, crystallize alternatives, make a choice, and clarify how the choice will be put into action. Following this is a stage involving implementation in which the individual adjusts after the chosen alternative is enacted. Tiedeman also noted that the process was not necessarily linear and irreversible, arguing that one might recycle through these stages at any point. Such recycling might occur when, for instance, alternatives failed to crystallize (leading one back to exploration) or the selected alternative failed to lead to a satisfactory implementation plan (leading one back to choice making or exploration). Vincent A. Harren further expanded this model to focus specifically on the decision making of college students and to include attention to elements of individual and contextual variability in the decision-making process. His model included four phases of awareness: needing to decide, planning, making a commitment to a particular course of action, and implementation of the chosen alternative.

Other descriptive models of decision making have focused on selected segments of the decision-making process. Seeking to understand what starts the decision-making process, one model suggested that discrepancy between one's beliefs about the world and one's plans for entering it leads to a dissonance that is reduced by initiating a decision-making process. Focusing on how individuals weigh and evaluate assembled information and alternatives, other theorists

offered mathematical models in which alternatives are weighted by combinations of valence, expected outcome, and probability.

### ***Prescriptive Models of Decision Making***

In contrast to the models of decision making that simply detail how a decision is made, there has been considerable effort directed to understanding how decisions should be made. In one of the earliest prescriptive models in the vocational domain, Frank Parsons argued in 1909 that the central task of career decision making was one of assembling information about oneself and about the world of work and using true reasoning to arrive at a match between the two sets of information. This model of a scientific, methodical, rational approach to decision making has been echoed and elaborated in a variety of prescriptive models of decision making.

John D. Krumboltz and his colleagues also offered a prescriptive model to help youth make decisions in a rational, logical manner. Their model both describes the steps in the process and also advocates for a systematic progress through those steps. Known by the acronym DECIDES, this model includes defining the problem, establishing a plan of action, clarifying values, identifying alternatives, discovering probable outcomes, eliminating alternatives systematically, and starting action. This model has similarities to several more generic models of effective problem solving proposed by P. Paul Heppner and others.

Other advocates of the methodical, rational model of the decision-making process focused on classical expected utility approaches. These approaches describe the best decision on which the decider gathers comprehensive information about alternatives, assigns utility or desirability weightings to each alternative, considers the probability of the outcomes of each alternative in a systematic manner, and selects the course of action associated with the highest expected utility.

While many prescriptive models offer a view of the best decision making as undertaken by thoroughly methodical, highly efficient, information processors, others have argued that this does not match well the experiences of most deciders. Itamar Gati, for example, offered a modification of the expected utility approach that better reflected how people manage and process the voluminous information involved in the decision-making process. His sequential elimination

model highlights how deciders can progress through a methodical, sequential process in which they identify the most critical elements of the decision situation, rank alternatives according to those elements, and use the results to narrow down the number of alternatives considered. Accompanying this model is a recommended strategy for helping individuals through the prescreening, exploration, and choice stages of the decision-making process.

Finally, it should be noted that although a variety of models have been offered about what the decision-making process should look like, much remains unknown about the process actually used by high-quality decision makers and about how the limitations of human information processing and judgment can be accurately represented in prescriptions about the decision-making process.

### **Variations in the Decision-Making Process**

In its most basic form, the career decision-making process entails the identification of alternatives, the gathering of information, the weighing of options, and ultimately the choosing and implementing of one course of action. Although this process may appear fairly straightforward, it has been noted that there is considerable individual variation how and how effectively this process unfolds in a given decisional situation. Efforts to understand this variability has led to a number of taxonomies of decision-making strategies or styles.

### ***Decision-Making Styles***

Decision-making styles refer to the characteristic ways in which different people behave in decision-making situations. The earliest efforts to identify these differences proposed trait-like categories of deciders who appeared to be planners, agonizers, delayers, impulsives, intuitives, fatalists, or compliant. From this perspective, it is expected that a decider who showed, for instance, impulsivity in choosing the first available alternative would display that same decisional behavior across all decision-making situations. The most widely used taxonomy in this tradition is that of Harren, who argued that decision making varies in the extent to which the individual assumes personal responsibility (versus assigning responsibility to fate, peers, and authorities) as well as in the extent to which

the decider is logical (versus emotional) in the decision-making process.

His model includes a rational style in which the decider takes individual responsibility; a systematic, logical approach (i.e., an intuitive style) in which the decider also takes individual responsibility, but primarily considers emotional factors often impulsively; and a dependent style in which responsibility is deferred to others and a passive posture is assumed.

Similar categorizations have been advanced that suggest that the noted differences in approaching and behaving in decision making were likely to emerge depending on particular situations. According to this perspective, a decider might be hesitant (procrastinates or postpones decision making) in one situation, while being intuitive (choices based on an inner feeling of rightness or inevitability) or logical (objective appraisal and selection) or compliant (passive; choice basis is expectations of others or self-imposed expectations) in another. Still other taxonomies have suggested that deciders vary in the way in which they gather information (systematically or spontaneously) and process information (internally or externally).

With these noted variations in individual decision making, there has also been a strong endorsement of a decision-making process that includes considerable autonomy and independence and that is approached in a rational, systematic manner. Research has provided some support for this endorsement: the rational decision-making style has been linked with better approaches to problem solving, to greater knowledge about self, to better progress in the overall decision-making process, and to greater progress in implementing selected alternatives. There is also some evidence to suggest that the systematic decider is more likely to have a solid sense of personal identity and less likely to experience career indecision.

Along with the endorsement of the rational style, the prevailing recommendation from the literature discourages use of a dependent or intuitive style. Indeed, the dependent or compliant decision-making strategy has been linked with less favorable or adaptive functioning: individuals with a dependent style have been shown more likely to commit to alternatives without adequate exploration, to show less progress in the decision-making process, to avoid problem solving, and to lack confidence in their problem-solving abilities.

Although the available knowledge indicates that a rational, nondependent decision-making style can be expected to be effective, there is also growing evidence

that such a style is not the only adaptive decision-making strategy. For example, in studies of interventions designed to help deciders, it has been shown that other decision-making strategies can prove helpful.

In a related vein, recent efforts have been made to highlight the possible adaptiveness of styles other than rational. Exploring the research on decision making and human judgment beyond the vocational domain, it has been noted that the rational, autonomous approach to decision making that is advocated may be neither possible nor desirable. From the perspective of information processing, there is considerable evidence that ordinary people and even high-quality decision makers simply do not engage in a comprehensive, dispassionate, systematic, isolated decision-making process. In addition, where emotion or intuition is regarded in the vocational domain as something to be minimized, these qualities can also be viewed as highly relevant sources of information about available alternatives. Furthermore, where reliance on others is seen in the career decision-making literature as a dangerous departure from necessary autonomy, studies of expert judges suggest that making use of the expertise, wisdom, and perspective of others is highly valuable in the decision-making process. Taken together, there is growing evidence that decision-making styles that are different from the traditionally advocated rational style may also have distinct benefits in the decision-making process.

### ***Variations From the Context of Decision Making***

Although early study of variation in decision making focused on qualities of the individual decider, there is also a growing recognition that the context in which decision making occurs is likely to play a major role in how and how effectively an individual proceeds. This recognition has arisen from the growing evidence that cultural and interpersonal factors are as influential as individual differences in shaping behavior. From a cultural perspective, it has been suggested that in contexts where individualistic values prevail, the role and value of others in the decision-making process might be minimal. However, in cultures where collectivist values prevail, the role played by others may be quite pronounced and the value of the role of others emphasized, even within a traditionally rational process. These differences have been observed in studies in which the more confident deciders from

individualistic cultures were those who did not use a dependent style, while the deciders from collectivist cultures were more confident only if they did use a rational style.

From the perspective of the interpersonal context of decision making, other emerging perspectives have focused on the role of others in the decisional situation. These perspectives portray the decider as embedded in a social context that shapes perceptions, defines behavioral options, and influences courses of action. Drawing from knowledge about the powerful relational contexts of human experience, it has been argued that it is too limiting to consider the role of others only from the perspective of dependency or compliance. Rather, a view of an individual's decision-making process experience would be far more complete if it included all of the ways in which the relational context aided, supported, hindered, impinged, and/or ignored the decider's task. Toward this goal, a number of scholars have begun to articulate the variety of ways in which perceptions, alternatives, and experiences in choice making situations are influenced by the decider's relationships. For example, an initial taxonomy has been offered to detail two important dimensions: how deciders use others in decision-making situations in more or less self-directed ways and how others involve themselves in the decision-making process. Efforts such as these are providing increasing confidence that the role of others in decision making may be quite valuable in an individual's decision making.

### Future Directions

Theory and research on career decision making to date has yielded a clear view of the basic steps of the decision-making process and has identified some of the effective ways in which decisions can best be made. Although this knowledge has been advanced based on what may be an unrealistic view of human information processing, newer models are emerging that will capture the best decision-making processes within the capacity of everyday deciders. Similarly, although many extant models of decision-making styles or strategies have placed priority on autonomy and rationality, newer perspectives are incorporating the importance of culture and context, and there is a growing recognition that there may be multiple "good" ways to proceed in decision-making situations.

## DICTIONARY OF OCCUPATIONAL TITLES

---

The *Dictionary of Occupational Titles (DOT)* was originally developed in 1939 by the U.S. Employment Service (USES) as a means to organize occupational information into one volume using a standardized format. It was produced to assist with job placement, employment counseling, and labor market estimations; the latest edition was published in 1991. With each revision, the number of jobs included fluctuated as markets and jobs change periodically. The 1991

edition included almost 13,000 general and 20,000 separate jobs. Each job is classified according to a 9-digit number, creating a taxonomy designed to ease use.

The first of the nine digits referred to one of nine occupational categories: professional, technical, and managerial; clerical and sales; service; agricultural, fishing, forestry; processing; machine-trades; benchwork; structural; and miscellaneous. These nine categories were further divided into over 80 occupational divisions, which were further divided into over 500 occupational groups, representing the second and third digits. For example, the professional, technical, and managerial category is divided into types (e.g., architecture and engineering), which are then further divided into additional categories (e.g., civil engineering, marine engineering). The middle three digits relate to ways of doing tasks: ways to deal with data (e.g., synthesizing, compiling) and people (e.g., supervising, serving) and how a person uses things (e.g., precision working, manipulating). These occupational classifications were based on assessments of tasks conducted by people in the particular occupation. The final three digits represent the alphabetical list of titles based on the previous six-digit code numbers and were unique to a specific occupation. Thus, two or more occupations could have the same initial six digits because they are in the same general area, but would differ in the final three.

In order to help job seekers, each of the occupations included a paragraph defining what an individual conducting that work would do. Readers could look up these occupations based on their purposes. For example, someone could review information in a field closely related to what they are already doing, in another industry, or simply by occupational title if he or she is interested in finding more information about a specific occupation. For 70 years the *DOT* has not only been used to match people to jobs, but also for disability decisions, educational program design, vocational rehabilitation, personnel classification, vocational research, counseling, and employee selection procedures.

The *DOT* is not published anymore largely as the result of budget cuts; an ever-increasing need for accurate, timely market information; and a realization that employers began searching for workers with abilities across settings or even across industries. The *DOT* is not used much anymore, except by government agencies to determine disability benefits such as by the Social Security Administration and by

companies working with insurance claims brought by injured workers. A newer computer-based vocational system run by the U.S. Department of Labor called the Occupational Information Network (O\*NET) is currently in use and offers more flexibility and can be updated more frequently. However, the *DOT* filled a need for decades, paving the way for newer systems to assist workers, employers, and market projectors.

## DISABILITY

---

*See* PERSONS WITH DISABILITIES

---

## DISCOVER

---

DISCOVER Career Planning Program from ACT, Inc., is a comprehensive computer-based career guidance system offered on the Internet for Grade 5 through adult. It includes inventories of interest, abilities, and values plus detailed information about occupations (civilian and military), majors, schools, financial aid, and the job search. The results of the career exploration process are organized in an online career portfolio that provides an ongoing record of career choices and a complete resume.

### History

DISCOVER traces its history from 1967 when JoAnn Harris-Bowlsbey, then Director of Guidance at Willowbrook High School, developed a computerized program for career counseling called CVIS

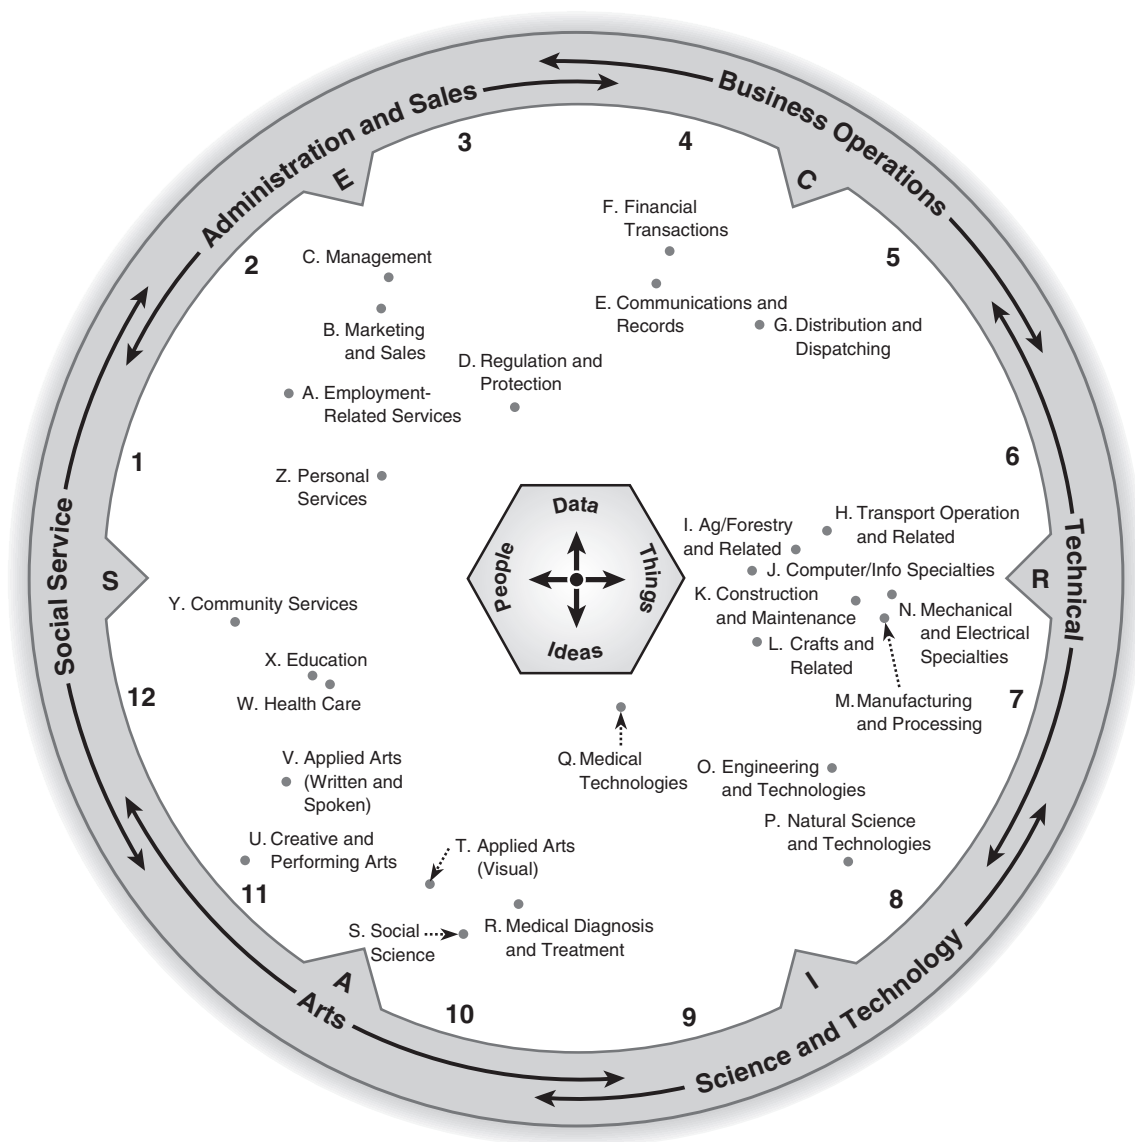

(Computerized Vocational Information System). The next incarnation of her work was called DISCOVER; and in 1982, the DISCOVER Foundation merged with ACT.

With each advance in technology and career development theory, new versions of DISCOVER were developed, and each included different components and features. The core features of DISCOVER remain research-based inventories organized around ACT's World-of-Work Map and quality information about occupations, majors, schools, and other career-related issues. These components are interconnected to

facilitate career exploration for users from middle school throughout the work life.

### Theoretical Model

ACT's World-of-Work Map provides the unifying theme for finding and understanding occupations. Two empirically based dimensions underlie the map: one dimension involves working with data versus ideas, and the other dimension involves working with people versus things. These four basic work tasks (data, ideas, people, and things) serve as the four

**Figure 1** World-of-Work Map

Source: ACT, Inc.

compass points on the map—just like a regular map. Six career clusters, paralleling John L. Holland's six career types, are also represented on the map. Within these clusters, 26 career areas are located on the map. Each career area contains occupations involving similar combinations of basic work tasks. Because both occupations and Holland-type score profiles can be located on these two dimensions, the map provides a simple, yet comprehensive bridge from persons (assessment scores) to occupational options.

### Assessments

People can be located on ACT's World-of-Work Map using a variety of assessments. DISCOVER includes the ACT's Interest Inventory (UNIACT), the Inventory of Work-Relevant Abilities, and the Inventory of Work-Relevant Values. Each inventory has been developed through extensive research, and psychometric information is available at no charge. Inventory results are expressed as career areas on the World-of-Work Map, and users are encouraged to explore and mark their favorites. For many users, the three inventories suggest different career areas. After taking multiple inventories, it is possible to compare the recommendations of these inventories. Occupations that match one's interests may not match one's abilities, and the occupations that are most likely to satisfy one's values may include others that have not matched one's interests or abilities. Counselors can use the comparison of these results to assist clients to understand competing issues related to the career choice process.

DISCOVER also accepts scores from EXPLORE, PLAN, and the ACT. Results of these tests, as well as many tests and inventories from other publishers, are used in DISCOVER to help people find their place on the World-of-Work Map. Combining achievement data with self-assessment provides another valuable opportunity for self-awareness. After completing tests such as these, the use of DISCOVER for career exploration greatly enhances the value of the assessment information.

### Information Components

Over 85% of users take one or more of the inventories in DISCOVER to help them find their place on the World-of-Work Map. DISCOVER encourages

exploration, with about 80% of users investigating descriptions of occupations. The occupational descriptions include detailed information about the occupation, training required, national and state salaries and outlook, and links to Web sites where more information can be found. Occupations are linked to majors and military occupations, both of which have detailed descriptions. Majors link to the schools that offer them, with a comprehensive description provided for each school. The majors and schools span the range from certificates for short training programs to graduate and professional programs of study. Virtually all accredited schools in the United States are included, and the information is updated annually.

Many other topics are also covered, such as financial aid, job search skills, and course planning. Links to information available elsewhere on the Internet allows users to pursue more detailed information on almost any topic. Users can compose a resume suitable for printing. They can also create a course plan. If local schools enter their own course list and graduation requirements, students can use this feature to select the courses they plan to take in high school that relate to their career goals. All of the information accessed in the program is tracked in the career portfolio, which provides a summary of features that have been used, decisions that have been made, and favorites that have been selected. Users are encouraged to keep their portfolio up to date as they change their career goals and educational plans.

### Navigation

All of these components are offered in an easy-to-navigate format. As an Internet-delivered program, DISCOVER may be used anywhere, any time, by both career seekers and family members. While this freedom opens up opportunities for parental involvement and nontraditional counseling settings, it also means that access is often unsupervised and the program must be usable without assistance. DISCOVER offers many types of assistance such as a tour, frequently asked questions, a site map, and detailed instructions on every page. The guidance of career professionals enhances the experience, and users are frequently encouraged to seek professional assistance, but comments from users indicate that most people navigate the program and find the information they are seeking without assistance.

## Professional Support

In addition to features for users, DISCOVER provides extensive support for counselors. Reports are offered to allow staff to assess the usage and value of DISCOVER, as well as review individual career portfolios. Sites that license DISCOVER can also customize the look and contents that their users see. Detailed manuals and guides are provided. Support materials include curriculum guides for middle schools, high schools, and colleges; they provide lesson plans with worksheets or activities to enhance class or group use of the program.

## Target Populations

Differentiation among users from Grade 5 through adult is addressed in two ways. First, some features are suppressed if they are not appropriate for certain age groups, based on the self-reported grade level of the user. None of the inventories in DISCOVER are appropriate for elementary school children, so they are not offered to users in Grade 5 or below. These users are encouraged to explore occupations by using the World-of-Work Map. If they can learn about the six clusters, then drill down through career areas to occupations to find some that interest them, they can begin to assess where they fit on the map. Grade 6 and up are offered age-appropriate versions of the interest inventory. Grade 8 and up are offered age-appropriate versions of the abilities inventory, which asks them to self-estimate their abilities. Although self-estimation accuracy probably improves with age, thinking about these questions can be helpful from middle school through adulthood. The values inventory is available for Grade 9 and up, based on indications that youth become increasingly aware of their values during the high school years.

The second method of differentiation is based on user's choice. Many features are more appropriate for more mature users, such as resume writing and apprenticeship information. But these features are available for use at any age, and the user can decide which topics are relevant. In fact, there is a feature called "Plan My Path" designed to help users decide which features to use.

DISCOVER is used in a wide variety of settings throughout the United States. It is used in schools, colleges, corporations, government agencies, military installations, libraries, prisons, and private counseling

offices. Each year close to a million people use the program.

DISCOVER is a computerized career guidance program that has been used by millions in Grade 5 through adult since its inception in 1967. It includes research-based inventories to guide the career choice process, a unifying theoretical basis, detailed career information, and a career portfolio summarizing each person's choices. It also supports career development professionals by providing usage reports, manuals, and curriculum guides. The Internet version makes all of these features available any time, anywhere.

## DIVERSITY ISSUES IN CAREER DEVELOPMENT

---

In the early 1970s, the field of vocational psychology began to focus on diverse factors related to career development. Recent trends indicate a sustained increase in the vocational psychology and career development literature pertaining to diversity issues since the early 1990s. These shifts have been fueled in part by the changing demographic patterns in society

and the increasing numbers of women and individuals from diverse racial and ethnic groups comprising the labor force. As the face of the labor force has changed over time, concerns regarding how the field has (a) understood and defined the career development process, (b) conducted vocational research, and (c) trained career counseling professionals for helping a broad range of individuals have been addressed. Today, diversity issues are considered to be crucial in understanding an individual's career development and decision-making process, and diversity issues have become a major focus within the field. As the U.S. population continues to grow increasingly diverse, career counseling professionals will need to be more responsive to the needs of this changing population. When addressing issues of diversity, it is important to note that these discussions should not be limited to race and ethnicity. Career counseling professionals also need to be attuned to the influence of gender, sexual orientation, ability status, socioeconomic status, and other societal and structural factors that influence career development in a variety of ways.

### **Diversity Issues**

As social beings, the environments within which people live and learn have an enormous impact on career development. The opportunities afforded to individuals, the resources at their disposal, and the social framework within which people live all interact and contribute to their sense of self and their awareness and knowledge of various career options. Thus, it is critical that a range of personal and societal factors be taken into consideration in attempting to understand an individual's career development process.

#### ***Individual Factors***

##### **Gender**

From the moment a child is born, a powerful and pervasive socialization process occurs in which girls and boys begin to learn what is expected and socially acceptable behavior based on their gender. This socialization process influences the type of play, leisure, and academic activities children tend to engage in and the development of children's schemas of appropriate gender roles. In addition, this socialization influences how individuals in the child's life will interact with the child and the types of behaviors that are reinforced. Researchers indicate that by the time children are

8 years old, they have developed a sense of what occupations are acceptable and unacceptable for their gender. Thus, children's experiences and gender role schemas have an impact on the types of occupations they consider as adolescents and young adults (e.g., nurse for women, doctor for men).

In the adult years, gender socialization continues to affect the career development of men and women in significant ways. For example, women who are employed outside of the house often struggle with balancing multiple roles and might feel that their roles and responsibilities at work and home are in direct conflict with one another. On the other hand, men may experience immense pressure to achieve at work and to be the main breadwinner for the family. The stress to be successful and to provide for the family to maintain a certain lifestyle may influence the types of career and positions that men consider appropriate. In addition, because a man's personal identity may be highly associated with his work, a man's psychological well-being may be at risk in the event of job loss or underachievement in the work setting. Though changing social norms and work opportunities have lead to an increase in the number of women entering traditionally male-dominated occupations (and to a lesser extent men entering female-dominated occupations), the impact that gender socialization has on career development continues to be a significant source of influence in the career selections and satisfaction of both men and women.

##### **Race and Ethnicity**

Race and ethnicity have been identified as factors that warrant consideration in the career development process. From both a personal and societal perspective, race and ethnicity can influence the types of occupations perceived as acceptable and accessible. For example, from a personal perspective, one's racial and ethnic identity (the extent to which one identifies as a member of a particular racial or ethnic group) can influence the types of occupations individuals consider as possible options. In part, this perception may be influenced by the type of learning experiences and opportunities to which racial and ethnic minority members have been exposed as well as the availability of role models from their racial or ethnic group in various career fields. From a societal perspective, racial and ethnic discrimination and oppression may lead members of racial and ethnic minority groups to eliminate occupations they perceive as inaccessible to

them. Thus, the impact of race and ethnicity on career development of diverse individuals needs to be examined from both a phenomenological as well as a societal point of view.

### **Culture**

Culture, the shared values and belief systems held by members of a particular group, influences how individuals view and interact in the world, and it also affects their behaviors, decision making, and goal identification. An example of a cultural value associated with different racial and ethnic groups is that of collectivism. Collectivism is the tendency for individuals to consider the well-being, wishes, and best interest of the group to which they belong (family or community) when making decisions. For example, a client whose culture values collectivism may consider the wishes of his or her parents or other elders in the family in determining what type of occupation to pursue. In contrast, individualism reflects the tendency to make decisions and choices within the context of what is best for the individual and is highly valued in Euro-American society. Thus, selecting a career based on personal interests and needs may characterize the decision-making process of individuals from individualistic cultures. Career counselors need to be aware of and respectful of the cultural context and cultural values that influence their clients' career development. Additionally, career counselors need to be aware of their own cultural values and beliefs systems and how these may affect the career counseling relationship. Career counselors' awareness of personal values and beliefs will also decrease the chances that they are imposing their values when assisting clients in their career development.

### **Sexual Orientation**

During the past decade, the career development of lesbian, gay, bisexual, and transgendered (LGBT) individuals has begun to receive increasing attention in vocational psychology. Understanding the complex relationship between sexual identity development and career development is critical when working with this population. Sexual identity development can be an extremely stressful experience for LGBT individuals as they may be dealing with gender identity confusion, negative societal stereotypes, and possible conflict with family and peers related to their sexual

identity. This developmental process typically occurs during adolescence, the same period of time during which young people begin to identify career interests and develop goals for their future. Thus, the career development of LGBT individuals may be adversely affected as a consequence of the time, energy, and affective resources that may be focused on their sexual identity development. Once LGBT individuals are ready to make career decisions, their choices may be restricted to occupations considered possible or appropriate options due to their sexual orientation. Additionally, they may eliminate possible occupational options due to real or perceived discrimination anticipated in certain work settings. Thus, sexual orientation and the unique issues that LGBT individuals encounter at work need to be attended to by career counseling professionals.

### **Other Relevant Considerations—Constructs**

Other relevant diversity issues that career counseling professionals need to attend to include, but are not limited to, the presence of physical or learning disabilities and immigration status and language proficiency. For example, individuals with physical or learning disabilities may have limited opportunities to engage in career development-related experiences and to develop effective decision-making skills, which can adversely affect their career development. Career counselors need to assess personal (e.g., self-efficacy), disability-related, and environmental constraints on the career development of individuals with a disability. When working with immigrant populations, particular consideration to the stressors faced by these individuals in a new and different society is critical. Attending to how immigrants are adjusting to their new environment, the stressors they are coping with, language issues, and immediate employment needs are critical as these factors may be affecting the career development process. In order to assist individuals in identifying and working toward realistic and achievable career goals, career counseling professionals must attend to the unique contextual experiences of their clients.

### **Social and Economic Factors**

Many of the traditional career development theories in the field have been criticized for being classist due to the basic tenets on which they are based. For

example, most Western theories of career development assume that individuals exercise volition in selecting careers, that career is central to one's life and identity, that universal definitions of constructs exist, and that opportunities are available to everyone. Ignoring the role of social and economic factors on the career development of individuals in our society can have detrimental consequences for the individuals with whom career counselors work, and disregarding these factors leads to continued class disparities.

### **Socioeconomic Status**

Socioeconomic status is unquestionably one of the diversity-related factors that has been widely understudied in the multicultural career literature, yet its significance in shaping career development cannot be overemphasized. Socioeconomic status has a significant impact on the lifestyles of individuals, the resources available to them, and the types of experiences individuals engage in, all of which influence one's social class. As such, the role of social class in the lives of individuals is especially important to understand because of its reciprocal relationship to work and more specifically the type of work that individuals have access to and to which they aspire. That is, social class can have a strong influence on one's career development, and in turn career plays a large part in determining one's social class.

Wherever one falls along the social class spectrum, there are many ways in which social class background plays an important role in career development. Social class background influences how counselors form attitudes related to success and career aspirations. For example, if a counselor believes that everyone can succeed if only a person works hard enough, the counselor might not address social barriers that might influence the career development of clients who believe that no matter how hard they try, they cannot make it through the system. Believing that talents and hard work are always rewarded or that everyone in society has the same opportunities for economic success places the responsibility of success and failure solely on the individual and ignores the presence of institutional barriers (e.g., discriminatory hiring practices) that can prevent an individual from achieving his or her goals. Social class may also determine whether someone has financial resources to pursue higher education, the social contacts and networks to locate jobs, and access to critical information that can inform career decisions.

### **Education and Academic Preparation**

Socioeconomic status also influences aspects of the environment that can affect the individual's career development. Economic capital (or lack of it) is associated with the quality of housing, neighborhoods, and schools individuals have access to. The quality of teachers, the educational resources available both at school and at home, the types of extracurricular activities offered at the school, and the expectations teachers have for students all contribute to the quality of education a student receives.

During the early years of schooling, a strong, quality educational foundation across the core academic subject areas, but especially math, science, and reading-writing, prepare youth for secondary and postsecondary education. In addition, coursework in the math and science areas has been identified as especially critical for entrée into highly prestigious, high-paying careers. A poor quality education can put youth at risk for not graduating from high school or may limit further educational opportunities down the road. Because education is highly linked to occupational status, it is important that all individuals in society have equal opportunities for receiving a quality education and that supports are available for those wanting to receive advanced levels of education.

### **Real and Perceived Barriers**

Real or perceived barriers related to socioeconomic status that can influence the career decisions and career development of individuals include discrimination; limited exposure to a range of careers; lack of role models from the community employed in a range of careers; lack of financial resources for education or training; lack of support from teachers, peers, or family; and lack of educational preparation. Individually and cumulatively, these environmental barriers can influence the internal beliefs one has regarding his or her ability to achieve his or her goals and can limit the types of careers that individuals believe are realistically attainable.

### **Career Counseling Models**

A number of models and frameworks have been proposed for providing culturally sensitive career counseling with culturally diverse clients, women, LGBT individuals, and individuals with disabilities. Significant components of these models include the attention placed on identifying cultural and contextual factors

that have an impact on individuals' career concerns and include the identification and selection of culturally appropriate interventions. For example, Fouad and Bingham's culturally appropriate career counseling model provides a seven-step process career counselors can follow when working with culturally diverse clients. The seven steps within the model include (1) establishing rapport and a culturally appropriate relationship, (2) identification of career concerns, (3) examination of the impact of cultural variables on the identified concerns, (4) establishing goals consistent with the client's worldview, (5) identifying culturally appropriate interventions, (6) decision making and implementation, and (7) follow-up. Career counselors are encouraged to become familiar with the various models available in order to inform their career counseling work with diverse clients.

### Implications

Race, ethnicity, gender, socioeconomic status, sexual orientation, ability status, and the resources afforded members of diverse groups significantly affect career development. By attending to contextual and societal issues related to diversity within the context of career development, career counseling professionals acquire a more comprehensive understanding of the needs of their clients and are better able to provide effective and culturally competent career counseling services.

The labor force continues to be highly stratified based on race, ethnicity, gender, socioeconomic status, and sexual orientation, and a hierarchy exists that differentiates careers based on status and prestige. As the field has moved toward adopting a social justice perspective, it is apparent that providing career interventions with individuals from diverse backgrounds can be an effective way to begin to address inequalities in our society. It is also important that career counselors advocate for changes in the world of work that are equitable and honor and value all workers, regardless of their backgrounds or positions.

## EMPLOYEE APTITUDE SURVEY

---

The Employee Aptitude Survey (EAS), used for more than 50 years in selection and career counseling, was developed to yield “maximum validity per minute of testing time” (Ruch, Stang, McKillip, & Dye, 1994, p. 9). Derived from earlier ability tests, it consists of 10 short tests that may be given singly or in any combination. There are alternate forms for nine of the tests. EAS is claimed to be easily administered, hand scored, and interpreted—although, in fact, advanced training or consultation is needed to interpret or use the EAS in selection. The Web site of the company that publishes the EAS ([www.psionline.com](http://www.psionline.com)) contains brief suggestions for use and interpretation of scores and suggests that further technical support is available via phone or e-mail. The tests may be administered in paper and pencil form or online. A technical report suggests that these differing modes of administration yield comparable results. Instructions suggest that group and individual administration are equivalent; data on other ability tests suggest that group administration facilitates performance on highly speeded tests such as the EAS.

The test themselves have not been revised since 1963. The *Examiner's Manual* is newly revised (2005), but the *Technical Manual* (1994) and *Supplemental Norms Report* (1995) are dated. A validation table is available on the Web site, but closer inspection reveals that it is drawn from the 1994 manual, which itself is based largely on older reports. Skippy norm sample detail limits the EAS's value in selection; local validation studies would often be required. Few EAS validity studies have been published in peer-reviewed

journals. A brief example (apparently hypothetical) uses the EAS to increase selection validity and achieve cost savings; the estimates are overly optimistic. Furthermore, the *Supplemental Norms Report* reveals ceiling problems across several tests, making the EAS unsuitable for use in some upper-level occupations.

The norm tables do not constitute validity data since the groups were not selected on some criterion of success. They may serve as rough guides in career counseling, showing clients where they stand relative to various occupational groups. Only the validity coefficients in the *Technical Manual* have been validated for such predictions. They are fewer in number, grouped into eight broad occupational categories. A meta-analysis suggests the EAS has predictive validity across several occupational and educational groups, but differential validity evidence (gender, age, and race) is not included. Only rough predictions about training or occupational success are possible.

Reliability data are limited to alternate form single-session administrations. Although the coefficients are impressive, they overestimate reliability, the tests being homogenous in content and highly speeded. No internal consistency data are presented, although internal consistency ratings would likely be high, given the above. Except for the Manual Speed Accuracy Test, no test-retest (i.e., stability) data are presented.

The EAS has a long record of usefulness in industrial selection and career counseling. Despite these criticisms, the EAS compares favorably with other multifactor ability batteries (e.g., USES General Aptitude Test Battery, Differential Aptitude Test,

Armed Services Vocational Aptitude Battery) when used to test clients seeking information about their abilities. The tests are short, easy to administer and score, and straightforward to complete. Interpretation can be a challenge.

## ENVIRONMENTAL ASSESSMENT TECHNIQUE

---

The Environmental Assessment Technique (EAT) was developed by John L. Holland and Alexander W. Astin to quickly and easily capture the dominant beliefs, functioning, and goals of the individuals within an organization, using Holland's six environmental models. The EAT consists of eight scales: Institutional Size, Aptitude Level, and six Personal Orientation scales.

### Theoretical Background

The EAT is based upon Holland's theory of vocational personalities and work environments, which suggests that people are both affected by and affect the environments in which they find themselves. His personality types and environmental models represent the bidirectional influence of person and environment. Both personality and environments can be classified using the following categories: Realistic, Investigative, Artistic, Social, Enterprising, and Conventional. Thus, by evaluating the proportion of each type of

people in an environment (the Personal Orientations scales), one can obtain a sense of the character of that environment. Complete descriptions of these categories can be found in Holland's *Making Vocational Choices*.

The EAT has the advantage of using easily available information that is quantitative in nature (thus facilitating comparisons) and heuristic (as the results produce a description of the goals, rewards, motivations, coping styles, and interests most evident and influential in a particular environment). The use of objective data lessens the likelihood of perceptual bias and complements data drawn directly from the population of interest, such as from the Position Classification Inventory.

### Utility

The validity of the EAT is moderate to high with reliabilities in this range over 1 to 5 years and appropriate convergent validity. Although originally developed for use in university environments, the EAT has also been used to evaluate the environment in middle schools, high schools, and the military and of college graduates transitioning to full-time employment. Organizational psychologists have encouraged its use in organizational consulting.

### Scoring and Interpretation

Originally, the scales for the EAT were compiled in the following manner. The Institutional Size scale consists of the square root of the number of students–employees in the institution. The Aptitude Level is taken from the mean score on a nationally normed test (or other measure of cognitive skill, such as found in the Occupational Information Network or the *Dictionary of Holland Occupational Codes*). The Personal Orientation scales are compiled in three steps. The first step is to obtain counts of the number of students in each major or individuals in each occupation. The second step is to aggregate the counts, using the first letter of the code for each major-occupation, according to their fit within Holland's classification of occupations or college majors. The third step entails calculating the percentage of the total majors that fall within each of the six personality–work environments.

The results will produce a Holland Occupational Code for the entire organization. The characteristics of the Personal Orientation scale with the greatest

percentage will have the most influence on the character of the institution as a whole. Interpretation of the resulting code is conducted in conjunction with the definitions from Holland's theory. Holland has developed dictionaries of coding schemes for both occupations and college majors in order to facilitate the use of this technique.

## EXPRESSED, MANIFEST, TESTED, AND INVENTORIED INTERESTS

---

No universally accepted conceptual definition of *interests* has emerged in vocational psychology. As a result, interests often are defined as what an assessment measures. At the most basic level, operational definitions of interests commonly focus on an individual's constellation or pattern of likes and dislikes for vocational, academic, and leisure activities, as well as for types of occupations, settings, and people. Donald Super organized these operational definitions into four methodological categories: *expressed interests*, *manifest or evidenced interests*, *tested interests*, and *inventoried interests*.

Frank Parsons, an early career specialist, introduced a parsimonious framework in his widely known book *Choosing a Vocation* that provided an impetus

for the measurement of interests. Parsons (1909) argued that individuals seeking to choose a line of work should engage in a rigorous process of self-study during which they consider how their “capacities, interests, resources, and limitations, and their causes” (p. 5) might best fit with the attributes of certain occupations. Parsons intended this process of self-study to occur with the aid of a counselor, and he offered a variety of innovative methods for counselors to assess a client's personal characteristics.

Among these methods, Parsons presented a questionnaire that asked respondents to simply identify and write down their interests as well as the nature of those interests. According to Super's classification system, Parsons's questionnaire elicited expressed interests. In other words, expressed interests are those that an individual is able to articulate via introspection without the assistance of a list of options. For example, in response to the question, “What do you want to do when you grow up?” one could state an occupation (e.g., medical doctor) or an activity (e.g., care for others). Expressed interests are highly subjective in nature and tend not to be limited to certain content areas or levels of specificity. Furthermore, expressed interests reflect how an individual perceives his or her interests rather than provide an objective and complete picture of his or her interests.

A more objective method of assessing interests, also proposed by Parsons, involved asking clients to report how they spend their time, particularly outside of work. For instance, if an individual spends his or her evenings reading novels and writing poetry, then these behaviors may indicate an interest in literature or the humanities. These manifest or evidenced interests have been described as those measured by observing or examining an individual's participation in activities. The most objective form of manifest interests involves direct observations of an individual's behavior over time, whereas the most subjective form involves an individual's self-reported activities.

In addition to reporting how one has previously spent his or her time, Parsons (1909) further suggested that individuals, particularly young individuals with little breadth of experience, should attempt to gather a variety of experiences to bring their “true interests and aptitudes into clear relief” (p. 12). This effort to accumulate a variety of work experiences with the intention of identifying one's interests was later known as *try out* activities. As Parsons and others have suggested, try outs are based on the hypothesis

that experience allows latent interests to emerge into an individual's awareness.

In yet another method of assessment, Parsons suggested that individuals should attempt to compare their memory of the content of certain lectures, plays, or books to that of other individuals such as friends and family. Implicitly, Parsons proposed that an examination of one's memory or knowledge of certain subject matter may indicate personal characteristics such as one's interests in certain subject matter or activities. Interests measured by an individual's knowledge of particular areas have since been classified as *tested interests*. Much of the research on tested interests is based on the notion that one's interests have a positive influence on learning. For example, if an individual has a strong interest in psychology, then he or she is more likely to give more attention to psychological subject matter than other academic subjects and as a result accumulate more knowledge of psychology. That is, interests are thought to influence learning by way of attention. In recent years, researchers have studied domain-specific knowledge, which includes tested interests, as a way to conceptualize knowledge that one accumulates over time as a result of one's constellation of interests, personality characteristics, and abilities.

In the 1920s, checklists and rating scales emerged as methods of measuring interests using surveys. Whereas checklists simply ask respondents to examine a list of activities and indicate those in which they have an interest in participating, rating scales ask respondents to rate the intensity or level of their interest for various activities. Checklists and rating scales evolved into what now are known as *interest inventories*. Interest inventories ask respondents to report their likes and dislikes according to a list of activities, school subjects, and occupations, and then the individual's pattern of likes and dislikes is aggregated into interest scales. Accordingly, *inventoried interests* have been defined as an individual's normative level of interest in a particular content area.

Inventories, and thus operational definitions of interests, became increasingly sophisticated as new methods of measurement were introduced. The four most frequently used methods of scale construction include the empirical method of contrast groups, clustering techniques, rational methods, and sequential methods. The empirical or criterion keying method of scale construction, developed by Edward Kellogg Strong, Jr. in 1927, involves contrasting interests of

certain groups of individuals to determine preferences that predict group membership. In other words, criterion-keyed scales indicate how consistent or similar one's likes and dislikes are to those of a particular group of individuals. Commonly used to measure interests of occupations, items (i.e., survey questions) that predict occupational group membership are aggregated to produce a single score. For example, an occupational scale constructed to measure the interests of psychologists would indicate the level of similarity between an individual's pattern of likes and dislikes and the likes and dislikes of psychologists in general.

Clustering methods of scale construction involve a statistical technique, such as factor analysis, that determines factors or dimensions underlying a group of items. In other words, preferences that can be explained by a certain factor or dimension are aggregated to generate a single scale score. Often, scales determined using a clustering method represent a homogeneous category of activities (e.g., mechanical) and are referred to as basic interest scales.

The rational method of scale development entails simply grouping items in accordance with a theory or rationale; thus, this method of scale construction is not empirical in nature. Proposing that interests can be described by six general types (Realistic, Investigative, Artistic, Social, Enterprising, and Conventional), John Holland's widely known and empirically supported typology is an example of a theoretical model that has served as a basis for the construction of rational interest scales. Interest scales also have been developed using the sequential techniques, which are a combination of construction methods. For instance, the General Occupational Themes of the Strong Interest Inventory (Strong) and the Orientation Scales of the Campbell Interest and Skill Survey (CISS) were developed using Holland's typology to initially select items and then using empirical data and clustering methods to finalize the scales.

The costs and benefits of the different modes of interest measurement tend to determine usage in research and applied settings. Interest inventories are arguably the most common form of interest assessment. Because there is little monetary or temporal cost for measuring expressed interests, career counselors often assess clients' expressed interests as part of an intervention. Due to the high cost of paying observers, interests are rarely, if ever, measured in research or practice via direct observation. More commonly, manifest interests are elicited in practice

through discussion concerning current and past vocational and leisure activities. Interest inventories, which offer objective, comprehensive, quantitative, and convenient measures of interests, are considered to be a comparatively cost-effective method of assessment. The Strong, CISS, Kuder Occupational Interest Survey, and Career Assessment Inventory are commonly used inventories that include general, basic, and occupational interest scales that provide a multifaceted profile of a respondent's interests. The Self-Directed Search also is a commonly used inventory that can be self-administered, self-scored, and self-interpreted. Other interest inventories include the Career Occupational Preference System Interest Inventory, Jackson Vocational Interest Survey, Unisex Edition of the ACT Interest Inventory, and Vocational Interest Inventory.

## GENERAL APTITUDE TEST BATTERY

---

The General Aptitude Test Battery (GATB) was developed by the U.S. Employment Service (USES) for use in occupational counseling, primarily by national agencies and in state employment offices. The measure was published in 1947, revised several times, and discontinued in 2002. The battery assessed multiple cognitive, perceptual, and psychomotor abilities as preferred rather than general mental ability when classifying people into jobs. (It is at variance with a competitor battery, the Differential Aptitude Tests, and other similar batteries by virtue of its inclusion of perceptual and psychomotor abilities.) The primary goal of the GATB was to match employee abilities to specific jobs. USES validated the test against some 66 occupational groups in five job families, only a small percentage of those for which it could be used.

GATB Form A was used operationally in 1947 with Form B, which was used for validation research and retesting. These forms were changed over the years. In 1983 Forms C and D were introduced. Spanish-language and nonreading versions were also available during that time period. Some reviewers during the early years of the GATB found the test manual lacking information needed for proper test administration, although the manuals for later forms were improved.

The GATB consisted of 12 separately scored and timed subtests that were used to compute nine aptitude scores. Test administration did not require a professional and took 2.5 hours. The test was appropriate for individuals in Grades 9 through 12 or for those in

the workforce. Subtests included Name Comparison, Computation, Three-Dimensional Space, Vocabulary, Tool Matching, Arithmetic Reasoning, Form Matching, Mark Making, Place (a pegboard test), Turn (another pegboard test), Assemble, and Disassemble. The subtests involve both verbal and quantitative reasoning and both verbal and performance measures. Some subtests were highly speeded and were appropriate for clerical positions. Aptitude scores are computed; most commonly used are cognitive (including general, verbal, and numerical aptitudes), perceptual (including spatial aptitude, form perception, and clerical perception), and psychomotor (including motor coordination, finger dexterity, and manual dexterity) composites. The meaningfulness of the tests comprising the measure was thoroughly considered; it was found that the cognitive subtests demonstrated reasonable construct validity in terms of convergent validity, the perceptual measures were substandard in this regard, and there had been too little research on the psychomotor measures to make an overall judgment. Some criticized the test because the aptitude composites are too highly intercorrelated. That is, some believed that the separate cognitive subtests of the GATB all measured the same thing or qualities that were so highly correlated as to be lacking discriminant validity.

The test was extensively used and researched in both employee counseling and selection, especially in state employment offices. In counseling settings it was probably best used in conjunction with a vocational interest inventory so that abilities and interests could be considered simultaneously. Its use was both widespread and controversial enough that the fairness of its uses was studied and published by the National

Academy of Sciences, as described in Hartigan and Wigdor. The primary issue related to group differences, often a concern for general ability tests. Because Whites scored better on the cognitive subtests than did Blacks by approximately one standard deviation, the National Academy of Science panel called for adjustments to scores depending on group membership, a highly controversial practice, or the use of within-group percentile scoring. Although such a practice is controversial, it eliminates very little of the test's utility for predicting job success, yet it provides a more diverse workforce. Also, concern had been raised over the use of the GATB's requiring relatively high levels of reading and arithmetic calculations with educationally and culturally disadvantaged persons. Furthermore, the original norm groups were limited by being both quite small and entirely male. The job classification system on which the test was based was also quite dated. The group differences coupled with the decline in unskilled and clerical positions probably led to the decision by USES to discontinue publication of the test early in the first decade of this century.

---

## HALL OCCUPATIONAL ORIENTATION INVENTORY

---

The Hall Occupational Orientation Inventory (HOOI) is an ambitious undertaking designed to aid career and personal exploration through the self-assessment of needs, values, interests, and abilities. Resembling a psychometric one-stop shop, items cover more dimensions at once than other tools used for similar exploratory purposes.

The HOOI was originally published in 1968 in three forms: an intermediate form primarily for students in Grades 3 to 7, a young adult-college form, and an adult basic form. Based on the doctoral dissertation of its developer, Lacy G. Hall, it is now in its fourth edition. There are three forms commercially available: Form II, which is primarily for junior high school students through adults who are not college bound; a Young Adult-College Form; and an Adult Form. All materials, including the 9-page reusable inventory booklet, onetime self-scoring response sheets, self-interpretive folder, manual, and a supplementary reader, *Choosing: Your Way*, can be obtained through Scholastic Testing Service, Inc. This entry will address only the Young Adult-College and Adult Forms.

These two forms contain 175 items that are wedged into 35 scales that are crafted into five scale arrays as follows: (1) nine Needs-Values Scales (Creativity-Independence, Information-Knowledge, Belongingness, Security, Aspiration, Esteem, Self-Actualization, Personal Satisfaction, and Routine-Dependence);

(2) six Career Interest Scales (People-Social-Accommodating, Data-Information, Things-Physical, People-Business-Influencing, Ideas-Scientific, Aesthetic Arts); (3) eight Job Characteristics Scales (Geographic Location, Abilities, Monetary-Compensation, Workplace, Coworkers, Time, Qualifications, and Risk); (4) six Choice Style Scales (Subjective External Authority, Objective External Authority, Subjective Internal Authority, Shaping-Autonomy-Self Empowerment, Interdependent, and Procrastination); and (5) six Ability Scales with the same labels as the Career Interest Scales.

The 35 scale scores are arrived at by summing Likert-type responses to the items on each scale and placing the totals on a self-interpreted profile sheet in the interpretive folder. This allows for the raw scale scores to be converted into one of three groupings: *low*, *average*, or *high*. Descriptive information regarding the scales is available in the interpretive folder.

The items are rationally constructed with three different Likert formats depending on the scale array. Needs-Values, Career Interest, and Job Characteristics scales use a 5-point format ranging from *most desirable* to *very undesirable*. Choice Style uses a somewhat odd 3-point scale with scores of *not like me* at 1, *like me* at 2 and *very much like me* at 3. The Ability scales use a 4-point format ranging from *weak* at 1 to *strong* at 4.

In spite of its potential usefulness, the HOOI has not elicited a strong research following because of the lack of any substantive data attesting to the reliability and validity of user scores. Moreover, normative data are lacking and the hand scoring of the large number

of scales is tedious and potentially error prone; it is not available for online administration and scoring.

The HOOI does have a following among counselors who note that clients find it simple to use and more comprehensive than other standardized career inventories. The instrument's questions force self-examination of a variety of occupational and lifestyle issues. Counselors can think of it as an introductory device that might spearhead in-depth counseling.

## HOLLAND, JOHN L. (1919– )

---

John Holland is primarily identified as a counseling psychologist whose main theoretical and practical contributions have been focused in the field of career choice and adjustment. He has been concerned with the choice and processes involved in selecting, adapting to, and changing occupations. His theory and practical contributions apply most directly to people throughout their working years, but are also relevant to school-age persons who are choosing colleges and selecting major areas of concentration.

### Empirical and Theoretical Research Themes

Holland's most impressive contribution to psychology was the combining of two important theoretical traditions, namely vocational psychology and personality.

In 1959, Holland published his article, "A Theory of Vocational Choice," in which he presented a theory that gave importance to personality as well as to the reinforcement value that specific environmental events could hold for an individual. He was one of the first major theorists to emphasize the critical importance of the interaction between vocational environments and individual differences and personality. He drew upon basic learning theory and modeling theories of personality development to inform others of these issues. In fact, his work anticipated by about 10 years the interest in personality psychology on the interaction between personality and situation in determining behavior.

To operationalize the personality types and model environments, Holland developed a number of inventories that represent a major applied contribution to the field. All of the Holland assessment techniques are practical and useful assessment devices. Initially he developed the Vocational Preference Inventory to define the personality types that he has studied over the years. The self-scoring and self-interpreted Self-Directed Search served to more comprehensively assess the personality types. Self-Directed Search is now the most widely used interest inventory in the world. To assess environments, Holland and Alexander Astin developed the Environmental Assessment Technique, and more recently Gary Gottfredson and Holland constructed the Position Classification Inventory. The theoretical person-environment framework has further been used to restructure the Strong Vocational Interest Blank, now called the Strong Interest Inventory. Related inventories developed to further define the personality types and model occupational environments include the Vocational Identity Scale and My Vocational Situation. More recently, Holland along with Gottfredson has developed the Career Attitudes and Strategies Inventory, another practical inventory to assess clients' internal and external barriers that may limit their career development.

A third major theme and contribution involves the use of his theory of personality types and work environments as a taxonomy for classifying people and jobs. Data from longitudinal studies, job analysis data, and vocational interest data have resulted in an extensive empirical classification of 13,000 occupations in the U.S. economy. All occupations now listed in the *Dictionary of Occupational Titles* (1991) may be classified using the Holland taxonomy. This has been accomplished in the *Dictionary of Holland Occupational*

*Codes* published by Gottfredson, Holland, and Deborah Ogawa in 1982 and revised in 1989 and 1996.

In summary, his theory, constructs, and operational definitions are extroverted, tough, practical, and compact. As Henry Murray noted some years ago, any assessment of the person is incomplete without some assessment of the environment. We cannot take the person out of personality, but at the same time, we cannot ignore the fact that environments, like people, have personalities and influence behavior. Holland's theoretical framework links the person, the environment, and behavior in a data-based framework to help people understand and cope with problems.

### Important Research Findings

At the heart of Holland's research has been the testing of his theory of personality types and work environments. Probably the most profound outcome of this research program is that his theory of personality types and work environments clearly works. For example, an overwhelming amount of evidence clearly indicates that individuals tend to choose, enter, and remain in occupational environments consistent with their interests and personality. He has shown that work satisfaction, and to some extent success in vocational settings, tend to be a function of person–environment fit.

Secondly, instrumentation development has been a very significant research contribution. Over the years, in testing his theory, he has developed the Vocational Preference Inventory, the Self-Directed Search, the Environmental Assessment Technique, the Position Classification Inventory, the Vocational Identity Scale, My Vocational Situation, and the Career Attitudes and Strategies Inventory. These inventories not only have operationalized the concepts of the theory, but also have further served in effectively assessing individuals throughout the world in vocational development and vocational decision making. In sum, Holland's theory, instruments, and research have served to explain vocational constructs in a straightforward way that is meaningful to a variety of people in a number of different environments.

A third important research finding is that his theoretical taxonomy may be used to describe every title in the *Dictionary of Occupational Titles*. This finding is demonstrated in the *Dictionary of Holland Occupational Codes* (1996), which is an extensive empirical classification of 13,000 occupations in the U.S. economy according to job analysis data accumulated by the U.S. Employment Service.

### Significant and Enduring Influences

Holland is one of the most productive researchers in contemporary psychology. His research has had a staggering influence on vocational psychology, personality, and organizational psychology. The enormity of his research findings are best presented in his book *Making Vocational Choices: A Theory of Vocational Personalities and Work Environments* published by Prentice Hall in 1973, revised in 1985, and republished by Psychological Assessment Resources in 1992 and 1997.

One significant and enduring influence of Holland's research is the finding that the choice of an occupation is an expression of personality. His research stream clearly indicates that individuals enter occupational environments because of their interests and personalities and remain in those occupations because of the reinforcements and satisfactions obtained through the interactions in that environment.

A second significant and enduring influence of his work is that the theory and inventories have greatly changed the face of vocational assistance. In other words, the theory and inventories have markedly improved the process of vocational assessment, the classification and interpretation of personal and environmental data, and the conduct of vocational counseling. Psychologists and counselors now have a theoretical framework to organize information about persons, work, and their interaction. The theory and research go a long way in organizing human behavior and occupational environments. This is further demonstrated by the fact that nearly all major interest inventories either use Holland's theoretical framework or are in some way linked to it.

A third significant influence of Holland's work is a function of self-directedness. His self-directed techniques afford individuals the opportunity to make their own choices. This is demonstrated in the self-administering and self-scoring Self-Directed Search assessment technique that has become popular throughout the world. Very few theoretical frameworks facilitate this kind of self-assessment strategy.

### Accolades

Holland has received a number of accolades for his contributions to the field. Within 10 years of his Ph.D. he received a research award from the American Personnel and Guidance Association (now the American Counseling Association). He is a Fellow of

the American Psychological Association for his contributions to both counseling psychology and educational psychology. He has received the E. K. Strong Gold Medal for contributions to interest measurement and the Eminent Career Award from the National Vocational Guidance Association. The esteem with which he is held is also indicated by his election as President of the Division of Counseling Psychology of the American Psychological Association and also by his appointment for one year as a Fellow at Stanford's Center for Advanced Study in the Behavioral Sciences. In 1980, he was honored by an entire symposium dealing with his contributions to psychology that was held at the national meetings of the American Psychological Association. A Festschrift volume was also prepared in his honor. More recently, Psychology Assessment Resources established an Outstanding Achievement Award in honor of Holland. This is titled the John Holland Award for Outstanding Achievement in Career or Personality Research and is awarded through Division 17 (Counseling Psychology) of the American Psychological Association. Finally, in 1995 Holland received the Distinguished Professional Contributions to Knowledge Award from the American Psychological Association. The award recognized his distinguished professional contributions to applied psychology and professional practice.

Holland is clearly world famous among counseling and vocational psychologists. His theory, concepts, inventories, insights, empirical research, and application have significantly changed the field of vocational psychology. Few professional people have been able to bring the innovative theoretical and applied understandings of human behavior to psychology in the way that Holland has. He is without question one of the two or three most important people in the history of the field.

## HOLLAND'S THEORY OF VOCATIONAL PERSONALITIES AND WORK ENVIRONMENTS

---

The origin of John L. Holland's theory of vocational personalities can be traced back to his 1966 publication *Psychology of Vocational Choice*, which was followed by four subsequent editions of *Making Vocational Choices*. With each edition, Holland built a more comprehensive theory of career counseling and tackled new issues arising from the complex relationship between human personality and suitable work environments. The theory is formulated around the fundamental observation that people possess different traits, behaviors, and interests that can be organized according to six groupings or types. The six types are called Realistic, Investigative, Artistic, Social, Enterprising, and Conventional (RIASEC), each of which characterizes a type of person who may gravitate to, choose, and enjoy a specific occupation or vocational area. In career counseling circles, it is common to hear a counselor refer to a Social or Investigative type person as a shortcut to describe someone who possesses clear, identifiable traits, personality characteristics, or behaviors. In a similar vein, the theory recognizes that work environments, the settings in which people work, live, and play, can also be organized according to the RIASEC typologies. It is theoretically appropriate to hear a career counselor describe a work function as a Conventional type job or a Realistic type activity. Through the use of the typological system and through the process of matching people who represent specific types with similar typed environments, career counselors try to enhance the likelihood that their clients will make satisfying career choices that lead to career stability and ultimately to career success and achievement.

## The RIASEC Model

### *Types of People*

The six types in the Holland theory describe multiple facets of the typee, which include personal characteristics, preferences, and tendencies. For example, the Realistic type person is considered to be rugged, robust, reserved, practical, and materialistic. People of this type are often inclined toward mechanical, physical, or technical activities where hands-on capabilities are paramount.

Each consecutive type demonstrates a sufficient degree of dissimilarity to the other types:

The Investigative type person is considered to be analytical, intellectual, complex, critical, and cautious. People of this type are often drawn to the sciences, quantitative pursuits, and research and scholarly activities.

The Artistic type is considered to be expressive, imaginative, intuitive, emotional, and nonconforming. People of this type are often drawn to art, writing, theater, and languages.

The Social type is considered to be friendly, warm, understanding, idealistic, and cooperative. People of this type are often drawn to teaching, counseling, social services, and other helping activities.

The Enterprising type is considered to be ambitious, energetic, sociable, assertive, and excitement seeking. People of this type are often drawn to politics, business management, leadership, and other entrepreneurial activities.

The Conventional type is considered to be conscientious, methodical, careful, orderly, and thrifty. People of this type are often drawn to accounting, banking, clerical, and computational work.

### *Relationships Between Types*

In addition to the descriptive qualities associated with the types, the RIASEC model also incorporates a spatial component that is depicted via a hexagon (Figure 1).

The distances between the types around the hexagon determine the degree of similarity or dissimilarity between the various types. Adjacent types on the hexagon are most related to one another, and opposite types on the hexagon are least related to one another. The hexagonal model also visually demonstrates a few other key concepts that are central to the Holland

**Figure 1** RIASEC model

theory. These concepts are calculus, consistency, congruence, differentiation, and identity.

### **Calculus**

Calculus provides the spatial foundation for the hexagonal model in that it refers to the degree of relatedness of all the types based on the distances between them on the hexagon. From calculus, one can more clearly understand the following assumptions of the theory as they apply to both people and environments.

### **Consistency**

Consistency refers to the assumption that adjacent pairs of types on the hexagon are most related and accordingly most consistent. For example, career clients whose tests show Social and Artistic as their two highest codes are considered to be more consistent than if they tested Social and Realistic as their two highest codes.

### **Congruence**

Congruence refers to the degree of match between one's type and the type of the work environment that he or she ultimately chooses. For example, persons who measure Artistic as their highest type would be most congruent in an environment that incorporates artistic activities, that allows for artistic expression, and that attracts other artistic people.

### **Differentiation**

Differentiation addresses a person's purity of type or whether that person clearly resembles one or perhaps two types, yet clearly does not resemble the other types. For example, a person is considered highly differentiated if he or she measures high on

Conventional and measures significantly low on all the other types. That same person could also measure highest on Conventional, next highest on Enterprising, significantly lower on all the other types and have both a consistent (due to adjacent codes) and well-differentiated profile

### **Identity**

Identity deals with the clarity of one's whole typological picture. A clear sense of one's career picture that includes an understanding of one's interests, goals, and talents as well as movement toward an accurate career environment is an indication of a firm career identity. Degrees of identity are highly related to the concepts of consistency and differentiation.

### **Types of Environments**

Just as personalities can be measured to determine typology, environments too can take on a typical character of their own. Holland determined that an environment's type was primarily determined by the constellation of personalities that made up the environment. For example, a hospital will present with a much different feel than will an accounting firm primarily because the people drawn to these environments act, relate, and perform work in very different ways. One can understand this dynamic by observing the differences between the hospital environment and the accounting firm environment. Since a hospital is largely staffed by physicians, nurses, and allied health professionals, its work culture is dominated by a unique combination of helpful, analytical, idealistic, intellectual, empathic, and curious people. In essence, it represents a combination of Investigative and Social types. In contrast, an accounting firm is largely comprised of accountants, bookkeepers, and administrative assistants who also define a work culture. This group of people is highly Conventional, so they tend to be careful, orderly, efficient, inflexible, practical, and thorough. Again, the work culture takes on the identity of the people who are in it.

### ***Other Defining Factors for Work Environments***

It is important to note that while work environments are largely defined by the people who are in them, this is not their only defining feature. Certainly,

the tasks required of the environment in order to complete the work have an impact on environmental type. Take for example the hospital with its doctors, nurses, and allied health professionals. The focus of the hospital is to diagnose and treat illnesses and to restore the health of sick people. This mission dictates that its culture is one of caring, responsibility, and curiosity about science and disease.

Work environments are not homogeneous in terms of their type. Some organizations are very large and complex, and therefore different units within the organization take on their own characteristics. Staying with the medical example, most large hospitals comprise separate units such as x-ray, surgery, patient care, business services, and social services. Each of these units attracts people with distinctly different work personalities by nature of the work responsibilities that are required, and in turn the work environment is shaped by the personalities of the people in the environment. It makes intuitive sense that the intense and critical nature of surgery feels very different from the warm, human interactions that occur in the social services area.

Power differentials in the workplace can also influence the culture and ultimately the type of the work environment. If the executives in a work unit exhibit a specific set of behaviors, attitudes, and interests, it stands to reason that they will value these same traits in their employees and both consciously and unconsciously reward these employees. This dynamic creates a workplace where employees to the best of their ability either conform to a type or be viewed as a less valuable. If, for example, the top executive in an organization has a high Realistic in his or her Holland code, then this person will typically value concrete achievements associated with the production of tangible objects, the creation of wealth, and opportunities to gain power and exert control. While it is highly probable that this executive may employ a number of Social employees to tend to necessary human interactions that require tact and diplomacy in an organization, he or she may not fully value the political contributions of these social types.

### **Assessment of Personal Type**

Methods exist for assessing types of people and types of work environments according to Holland coding. In the case of the former, a Holland profile can be determined a couple of ways: (1) utilizing a

well-constructed quantitative measure such as the Self-Directed Search or Vocational Preference Inventory that evaluates a person's interests, competencies, and self-ratings on multiple dimensions and assigns a code or (2) evaluating a person's current or desired career or position and assigning a code based on the work characteristics of the position. The Position Classification Inventory is a formal questionnaire of 84 items designed to assign Holland codes to various positions based on the unique work-related activities and tasks associated with a job.

It is important to note that while the Self-Directed Search is the instrument that is most closely aligned with and derived from Holland's theory, another widely utilized career instrument, the Strong Interest Inventory, also makes use of the Holland typological system. The selection of a method for measuring a person's type can vary depending on the goals of the career client, the training and ability of the career counselor, and the time and resources available to both parties.

### Assessment of Environmental Type

A method has been developed by Holland and Gary D. Gottfredson to measure the type of a work environment. This method is based on capturing the typical profiles of the people in the environment, or the inhabitants of the work environment. By applying codes to the people in an organization according to their occupational roles, training, or education, one can determine the dominant type within the environment. This method, known as the Environmental Assessment Technique, can be applied to any work environment, and it can generate an absolute number of types for an environment or a percentage of types based on the total distribution.

A resource was recently developed by Holland and Gottfredson that categorized all the entries from the *Dictionary of Occupational Titles (DOT)* according to a three-letter Holland code. This *Dictionary of Holland Occupational Codes* utilizes job analysis data to prescribe a corresponding three-letter code to the positions in the *DOT*, allowing for a more complex inventory of organizational type based on a three-letter profile rather than one primary type.

### Matching Person to Environment

The notion of matching people to environments can be broadly conceptualized to include environments

that go well beyond occupational responsibilities and work cultures. Person-environment interactions can apply to the fit between children and parents, students and neighborhoods, students and primary and secondary schools, adults and their social circles, and adults and retirement activities. There is a developmental component to the theory in that the degree of matching, or congruence, between person and environment in any of life's stages can profoundly influence levels of contentment or stress and frustration. In response, new decisions are made that ideally draw upon past experiences to create future situations that are more compatible and congruent. Take for example a student who decides to major in premed because he or she is drawn to being a physician out of a desire to help people, have a status position, and make lots of money. During the first year of college, the student encounters difficult science courses and realizes that he or she is not really congruent with science due to a lack of genuine interest in biology, chemistry, and physics. Consequently, the student modifies his or her choice of major to include potential majors where he or she can help people and make sufficient money, but not in the field of science or medicine. At this point, the student may ultimately choose psychology, human resources, or public administration where new interests and goals can be realized. In a short amount of time a shift has occurred in large part due to the developmental process of maximizing congruence.

### Research Support

Holland's theory of vocational personalities and work environments is a mature theory in that it has been widely researched for a period extending beyond 35 years. Evidence has generally supported the formulation of the Holland types; however, it has been concluded that the hexagon itself is much less symmetrical and exact than the drawings might depict. Nevertheless, the RIASEC ordering does hold true, and it has presented us with a model that is clear, practical, and highly amenable to vocational assessment. Other significant, yet secondary parts of the theory such as differentiation and consistency have received less compelling support since research results have been mixed. The environmental models have received the least attention by researchers, and the categorization of jobs by type remains a complicated process that varies according to the methods by which workers and jobs are measured and analyzed.

## Practical Applications

Perhaps the hallmark of Holland's theory is that it is user friendly. Psychological theories are often complex in both theory and in practice, yet Holland has managed to keep the end user in mind when developing his theory of vocational personalities and work environments. The RIASEC coding allows for a clean and simple method for assigning typologies to people, their current jobs, their career aspirations, their work culture, and a host of environmental factors. From the perspective of the career counselor who sees clients for a limited number of appointments, Holland's theory provides an efficient and effective method for making predictions about satisfaction in many work arenas.

## INTERNATIONAL APPROACHES

---

The term *career counseling* can be used in a narrow sense, addressing only a one-on-one or group verbal process and designed to assist counselees to explore, clarify, and understand their personal characteristics, their career concerns, and the behavioral options available. Career counseling can also be used in a wider sense, as a term that summarizes the processes and techniques that may be implemented as part of the career counseling process (e.g., assessment, information about job options, computer-assisted career guidance programs, self-directed exercises, Internet Web sites) to assist counselees to acquire knowledge, attitudes, and skills and to take actions relevant to their career concerns. Often in an international context, the term used as the equivalent of career counseling is *career guidance* or a term used in a native language that embraces elements of career counseling.

### **Career Counseling: A Worldwide Process**

Although career counseling and related interventions have become virtually worldwide in their availability for certain consumers and for selected purposes, there is not one model of career counseling extant across the world. There are many variations in approaches to the processes described as career counseling. Indeed, an increasing number of nations are developing their own indigenous models of career counseling rather than importing a model from another nation.

The nature of career counseling in specific nations is often a function of such factors as whether practitioners of career counseling are trained in a formal, academic setting or in a series of brief workshops; whether career counseling is primarily a function of government policy and legislation and a centralized provision of government or decentralized to many private entrepreneurs who deliver such services; whether there are differentiated career counseling services available to different groups of counselees or whether career counseling is available to any person who wishes such assistance; whether the provision of career counseling is augmented by the availability of online, Internet, computer-mediated career guidance systems or not; and whether the outcomes associated with career counseling are implemented in relation to particular theoretical models, cultural perspectives, or less systematic origins. Some brief examples will illustrate the range of emphases in career counseling among nations.

### **International Approaches: Examples**

Australia—a large nation with scattered populations across great geographic distances and with relatively few career counselors outside of urban areas to meet the demand for career counseling on a face-to-face basis—has provided many self-help resources, using audio, video, and computer technologies; the provision of employment information by telephone help lines and a nationwide telephone information service for career decision making that includes 3- to 5-minute spots on career planning, information, and

adjustment; and a national job network of more than 300 private, community, and government organizations with which the Australian government contracts to provide flexible and tailored assistance to job seekers from job matching to intensive assistance. Increasingly, career development in Australia is linked to lifelong learning and projects the practitioner of the future as a career development facilitator who assists individuals to plan and develop their career. Currently, there are initiatives that focus on the formulation of national quality standards for career practitioners, policy statements that affirm career education in school curriculum, and the development of resources about career activities for parents, school principals, and career advisors.

Canada has made many contributions to theory and practice in career counseling. They include the application of constructivist theory and narrative counseling to career counseling; the concept of active engagement in the creative interaction between career counselors and clients; group employment counseling; peer career counseling and the use of distance education to facilitate career planning; conceptual models of unemployment, its affects, and the role of career counselors in dealing with such problems; blending of counseling theory and the cultural traditions of First Nation peoples; the use of technology to provide career counseling and mental health interventions to widely scattered schools and communities in Newfoundland, Northern Canada, and Labrador; and the development of competencies that career counselors need to acquire in order to practice.

Denmark has made major commitments to the availability of career guidance at all educational levels and through adulthood. Career education begins at Grade 1 and continues until the end of compulsory education and is then available in higher education. Career education is integrated into academic curricula. Career development services are extensive and provided across the life span, primarily by teachers on a part-time basis. For adults, Denmark has instituted one-stop centers, known as counseling houses, in which career counselors offer different types of career counseling and related activities for users including information and counseling for training, educational options, and alternative job opportunities; training and improvement of job search skills; and information on the labor market and different wage, subsidy, and training schemes.

Japan, as a result of the dismantling of its lifelong employment system, the increasing numbers of school

dropouts, and school graduates without full-time employment has recently developed a policy to institute career education programs in schools and in higher education to help students learn to take responsibility for their decision making and their career planning. In addition, earlier than many other nations, Japan has instituted a three-tiered system to identify the level of need for career assistance of clients, on a continuum from largely self-help to intensive assistance in the National Network of Public Employment Security Offices. They also provide a national computer-assisted information system of labor supply and demand that is used as a support process to career counseling.

South Africa's history is unique in its legislated policy of apartheid that segregated citizens by race. When the apartheid regime was defeated and replaced in 1994, it was clear that the social context under which people of all races had lived and negotiated their place in society had to be re-created and that the psychology of despair had to be replaced with a psychology of hope, equality of opportunity, and economic and social equity. Among the large list of economic, educational, and social reforms that were instituted was career guidance. Part of the content of career guidance is assistance to adolescents of the formerly segregated racial groups to come to terms with their identity in a situation of rapid social and economic change.

Many college students who were previously denied access to higher education are now in integrated universities, where they experience anxiety, fears related to academic work, and low self-confidence. They are being provided workshops dealing with career and study skills, career information, job seeking skills, individual and group counseling, testing, the availability of liaison with potential employers, assistance with selection of a major, test-taking skills, time management, decision-making skills, and job search skills.

Public employment services in their career development work with adult job seekers to increasingly use self-directed information and assessment, and life skill training programs including career guidance components, and assessment and counseling.

## Future Outlook

International approaches to career counseling are diverse in their purposes, processes, and content. They reflect national differences in cultural traditions,

in the perceived career concerns of citizens and immigrants, the degree to which career counseling and related services are systematically or randomly implemented, the characteristics and training of those who provide them, and the policies and legislation that support career counseling. Career counseling or an equivalent term is now in place in some form in most nations. In a world of rapid change in the availability of work, its processes, and its content, growth in the development of new theories of career behavior, professionalization and competency standards for career counselors, and the availability of career counseling seems inevitable.

## INTERNATIONAL ASSOCIATION FOR EDUCATIONAL AND VOCATIONAL GUIDANCE

---

The International Association for Educational and Vocational Guidance (IAEVG) is a worldwide educational guidance and counseling professionals association representing individuals as well as national and regional associations concerned with educational and vocational guidance on all continents. It currently has over 20,000 individual and institutional members, including careers practitioners, consultants, and university professors and lecturers. The objectives of the organization are to promote and improve international communication between people and organizations active in educational and vocational guidance; to encourage the continuing professional development of ideas, practice, and research in the field of guidance and counseling; and to collect and disseminate information on the latest educational and vocational guidance practice, study, and research.

### History and Governance

IAEVG was founded in 1951 in Paris. The original objectives of the organization, which are still relevant today, were to provide educational and careers guidance professionals with the opportunity to exchange views and experiences and to benefit from mutual exchanges and experiences and to create an international resource for information on guidance matters.

The IAEVG Board is elected by the membership and includes six executive members: the president, three vice presidents, a treasurer, and a secretary general. Electronic online elections are held every 4 years and are led by the secretary general. Any major policy changes are agreed at the organization's general assembly, which is usually held every 4 years. Day-to-day management and services are handled by the IAEVG's international administrative center in Ottawa, Canada.

### Professional Services

IAEVG provides a number of professional services to its members and other interested parties: (a) a professional community and networking, which include worldwide conferences and networking meetings that are held annually and attended by members and nonmembers from all continents; (b) publications, including a regular newsletter, which is produced in four languages, and the *International Journal for Educational and Vocational Guidance*, both of which are produced several times a year and are free to members; (c) international counselor competencies for vocational guidance practitioners, a new service that enables members to gain international accreditation and certification for their professional work; (d) IAEVG's ethical standards support the quality of guidance delivery and services, as well as providing guidance on appropriate behavior toward clients.

Research is a key area of focus, and IAEVG has completed a number of pieces of work for the United Nations Educational, Scientific, and Cultural Organization, including a study of "Vocational Guidance for Equal Access and Opportunity for Girls and Women

in Technical and Vocational Education" and a joint publication produced with the International Association for Counseling, "New Roles and Challenges for Guidance, and Counseling."

There is ongoing international cooperation between IAEVG on study projects with the Organisation for Economic Co-operation and Development, the European Union, and the International Labour Office.

## JACKSON VOCATIONAL INTEREST INVENTORY

---

The Jackson Vocational Interest Inventory (commonly known as the Jackson Vocational Interest Survey or JVIS) is a standardized, normed career interest test that was first published by Douglas Jackson in 1977 after 8 years of research on vocational roles and styles. With the use of factor analytic and related multivariate techniques, Jackson created a unique career assessment tool, published by Sigma Assessment Systems.

The test consists of 289 pairs of statements describing occupational activities. Using an ipsative-choice A–B model, the user will make choices that result in normative scores on 34 work roles and styles scales. The test requires less than an hour to complete. As is stated in the *JVIS Technical Manual*, the internal consistency reliability from the most recent analyses ranged from .54 to .88 with a median of .72 for the Basic Interest Scales and from .70 to .93 with a median of .88 for the General Occupational Themes. Test–retest reliability coefficients based on an interval of 4 to 6 weeks ranged from .69 to .92 with a median of .82 for the Basic Interest Scales.

The resultant profile contains four major components: (1) Basic Interest Scales, (2) General Occupational Themes, (3) Similarity to College Students, and (4) Similarity to Job Groups. The JVIS is the only standardized career assessment tool to include the Similarity to College Students scales, which provide a unique opportunity for the career practitioner to

compare the client's interest in the training and practice of a work sector.

There are four versions of the JVIS Report. The Basic Report is hand-scored and results in only the Basic Interest Scales. The full report, containing all of the four major components, can be generated through mail-in scoring, onsite scoring software, and Web-based scoring.

The Web-based version, first published in 1996, has provided a powerful career-assessment tool. Depending on the printer used, this version generates a 25-page hypertexted profile, which is PIN-protected to the user. The profile contains hotlinks to professional Web sites related to the high-scoring job groups. The last part of this report, titled “Where to Go From Here,” contains Web-based resources and books that assist the user in pursuing further career research.

The JVIS has been effectively used by career practitioners for clients in the full range of career development: adolescents, career transitioners, and retirees. Significant research on the General Occupational Themes by Marc Verhoeve, cybertraining consultant for Sigma Assessment Systems, has resulted in some innovative applications in team management and group counseling. The Web-based JVIS is now used worldwide directly by clients and by career practitioners. Global training is provided by Sigma Assessment Systems utilizing a teletraining model.

## Job Loss

---

Job loss is a stressful life event in which employees involuntarily lose their current job, marking the start of a state called unemployment. Historically, job loss has gained research attention from several academic disciplines including economics, sociology, and psychology. From the psychological perspective, job loss research can be categorized into two major streams. The first research stream concentrates on documenting the detrimental impact of job loss. The second research stream focuses on how unemployed individuals cope with job loss and related institutional efforts that assist in the coping process.

### Detrimental Impact of Job Loss

A large body of research has linked job loss to reduced psychological well-being (e.g., increased depressive symptoms, reduced self-esteem and perception of competence, elevated anxiety and hostility, lowered life satisfaction, increased suicidal attempts, and worsened relationship with family members and friends). Research also shows that individuals who have lost their job may experience a decline in their physical well-being as well (e.g., increased self-report of physical symptoms as well as actual symptoms). In addition, some empirical evidence suggests that

unemployed individuals' well-being is improved shortly after they are reemployed.

M. Jahoda theorized that work serves several manifest and latent sociopsychological functions. An example of manifest function is earning income, while an example of latent function is the social identity endowed by employment. Job loss places these critical functions in significant jeopardy, which in turn leads to reduced well-being. R. H. Price has similarly argued that both economic hardship and eroded identity are two critical mediators of the above job loss–well-being link.

### Coping With Job Loss

According to a recent meta-analysis conducted by F. M. McKee-Ryan, unemployed individuals who possess some key characteristics or factors tend to cope with job loss relatively better than those who do not. These key characteristics include the following: lower career commitment-involvement, more positive self-regard, greater social support, greater financial resources (both objective and perceived), better time structure (able to organize time so as to retain the sense of purpose in life), internal attribution (blaming others for job loss), higher reemployment expectation, and more job search activities. These characteristics were similarly conceptualized by J. C. Latack in her career transition model as factors that enable unemployed individuals to transform job loss into career growth.

It is worth noting that government, unions, and organizations have been increasingly proactive in recent years in helping unemployed individuals (or soon to be unemployed) to better adjust to job loss through combined effort in legislation, government policies, and benefit and training programs. Research suggests that such efforts are modestly effective.

### Future Directions

With continued globalization and shifts of economic focus, job loss will remain an important topic in vocational psychology. Future researchers should implement longitudinal designs more frequently and obtain larger samples. Interdisciplinary research that goes beyond the psychological perspective is greatly needed. Additionally, job loss research in non-Western societies should prove promising in advancing both theory and practice.

## JOB SATISFACTION AND GENERAL WELL-BEING

---

With the emergence of the field of positive psychology, increasing attention has been paid to factors contributing to general well-being. Job satisfaction has been identified as a major component of general well-being. Meta-analysis has found a correlation of .44 between measures of job satisfaction and general well-being. Given the many life areas impacted by work, it has been argued by some that job satisfaction may contribute more to nonwork related life satisfaction than the obverse. Unfortunately, only limited research has been conducted to explore the specifics of the relationship between job satisfaction and general well-being. However, person–environment fit models, such as the theory of work adjustment (TWA), appear to offer a solid starting point for such inquiries.

### Goal Attainment

Discussions of general well-being often emphasize the importance of goal directedness and goal attainment to well-being. Given the extensive person–environment fit literature demonstrating significant

relationships between job fit and job satisfaction, it has been suggested that these models might provide direction regarding which goals to aim for and provide an aid for understanding the motivation to achieve one's goals. Currently, TWA is the person–environment fit model that is most amenable to making linkages between job satisfaction and general well-being. TWA views work as an interactive and reciprocal process between the individual and the work environment. In simplest terms, individuals may be viewed as fulfilling the labor requirements of the work environment in exchange for the work environment fulfilling a wide range of financial, social, and psychological needs for the individual. The TWA instrumentation developed to operationalize job satisfaction uses 20 dimensions: ability utilization, achievement, activity level, independence, variety, compensation, job security, working conditions, opportunity for advancement, recognition, authority, social status, coworker relations, social relevance, moral values, company policies, supervision (human relations), supervision (technical), creativity, and responsibility. Clearly, these dimensions reflect a mixture of both motivating factors and end goals.

### Hedonic and Eudemonic Perspectives

Most models of well-being may be categorized as either *hedonic* or *eudemonic* in perspective. The hedonic perspective defines well-being in terms of pleasure attainment and pain avoidance. The eudemonic perspective focuses on meaning and self-realization and defines well-being in terms of doing what is worthwhile. Although, the reinforcer dimensions of TWA reflect aspects of both the hedonic and eudemonic models, given the model's overall emphasis on satisfaction of needs, one might conclude that it leans more toward the hedonic perspective. However, structural analysis of the 20 reinforcer dimensions suggests there are six underlying dimensions or values. These values have been labeled *achievement*, *comfort*, *status*, *altruism*, *safety*, and *autonomy*. Achievement reflects making use of one's abilities and feelings of accomplishment. Comfort reflects feeling comfortable and an absence of stress or distress. Status reflects gaining recognition from and/or having authority over others. Altruism reflects helping others and having a sense of doing good deeds for others. Safety reflects an appreciation for structure and order and an absence of unpredictability. Autonomy reflects

being independent and feeling in control. Viewed on this level, TWA appears fairly balanced between eudemonic and hedonic perspectives of well-being.

### Extrinsic and Intrinsic Motivation

Well-being researchers have differentiated between *extrinsic* and *intrinsic motivation*. Intrinsic motivation refers to doing an activity for the inherent satisfaction of the activity itself. In contrast, extrinsic motivation refers to doing an activity to attain some separable reward. This closely parallels the concepts of intrinsic and extrinsic job satisfaction in TWA. In TWA, intrinsic job satisfaction reflects aspects that are inherent to the job itself (e.g., feelings of accomplishment), and extrinsic job satisfaction reflects aspects that are not inherent to the job itself and that are usually under the control of the work environment (e.g., salary). It should be noted that in the well-being literature, it has been argued that individuals who are motivated intrinsically tend to experience greater levels of well-being than individuals who are extrinsically motivated. However, TWA makes no differential predictions; job satisfaction arises from the degree of correspondence between worker needs and job reinforcers regardless of whether the most salient of these dimensions are categorized as being related to extrinsic or intrinsic job satisfaction.

### The Social Ecological Approach

Rudolph Moos's social ecological approach (also referred to as the life domains model) proposes that individuals may be conceptualized as existing within a constellation of overlapping environments, or *life domains*. Some of these domains are self, marriage, family, friends, work, and health. Moos developed 10 Social Climate Scales to characterize the most salient dimensions found across a range of domains. Although specifics vary from domain to domain, Moos found that the broad categories of relationship, personal development and system maintenance, and system change are cross-cutting. This finding is considered by some reviewers to be of major importance to the well-being literature. The relationship dimensions assess the degree people in a given setting support one another and feel free to express themselves openly. The personal development dimensions assess basic goals of a given setting and how personal development and self-enhancement occur in that setting. The

system maintenance and system change dimensions assess the clarity with which an environment states its goals, how it maintains control, and how it responds to change. The TWA need-reinforcer dimensions may be mapped onto Moos's three cross-cutting categories. Structural analysis of the six TWA work values suggest that they may be grouped into internal, social, or environmental reinforcer areas, categories whose interpretation echoes those of the cross-cutting categories proposed by Moos.

### Value Contrasts

Further structural analysis suggests that the six TWA values form contrasts. Achievement contrasts with comfort. On one hand, it is often not possible to attain difficult goals without stress, sacrifice, and discomfort. On the other hand, a comfortable, stress-free life may come at the cost of giving up ambitions. Altruism contrasts with status. Altruism focuses on the well-being of others, whereas status focuses on self-advancement and self-promotion. Finally, autonomy contrasts with safety. A highly autonomous person depends upon him- or herself independent of environment. A person with high safety needs depends on the environment to provide order and structure, while also depending on retaining control over the choice of environment to be in. These value contrasts have the potential to help individuals understand value conflicts, experienced both internally and in interaction with environments, and highlight that choices and/or compromises may need to be made when seeking either job or general life satisfaction.

---

## JOB SHARING

---

Job sharing, sometimes called work sharing, generally refers to the practice of having two or more people share a single full-time position, each working part-time. It can also refer to two or more people sharing a single budget line, but doing unrelated work.

Job sharing has been applied as a solution to several different situations that influence the availability or desirability of full-time employment. It has been identified as a way to help people balance work and family commitments, to provide access to employment for people with disabilities, to ease the transition of retirement and the training of new replacement employees, and to help employers minimize layoffs. There is some evidence that job sharing is efficacious in terms of economic impact as well as beneficial to employee morale and productivity.

### Job Sharing for Work–Family Balance

The impact of work–family conflict has received considerable attention, particularly in the last 20 years as women have increasingly entered the workplace and more families have become dual-career or dual-earner families. Research has generally demonstrated that increased conflict between work and family demands has been associated with decreased satisfaction across the work, family, and marriage domains.

Job sharing is one of several workplace family-supportive policies that have demonstrated appeal among workers who are attempting to minimize family–work conflict. There is some evidence that women view job sharing as a more important option than do men. However, family-supportive work resources appear to increase both job and family satisfaction ratings for both men and women. Furthermore, job sharing and other family-supportive practices have been viewed by parents as most important in dealing with work–family conflicts that interfered with job goals rather than with family goals.

Although family-supportive workplace practices have been examined in recent research and calls have been made for further study of job sharing and flextime practices, the specific option of job sharing has received limited attention. This may be due at least in part to the relative infrequency of job sharing. In a national survey of 1,057 employers, the Families and Work Institute found that 37.5% of responding companies provided job share opportunities, compared to 55% that allowed employees to periodically work from home and 68% that allowed flexible scheduling. However, job sharing was the most frequent flexibility option under consideration for future implementation, suggesting that it may become more generally available for employees seeking to balance work and family demands.

*The Chronicle of Higher Education* has run several stories on job sharing options in the past decade, noting the increased demand for family accommodations among faculty and the benefits to college administrators who need to attract faculty couples. There is anecdotal evidence of increased job sharing among faculty members, particularly in smaller colleges. Testimonials about these experiences suggest that the costs, which include reduced salaries and challenges to earning tenure, are outweighed by the benefits of flexible employment for the majority of job sharers. Research into the experience is certainly warranted.

### Job Sharing to Accommodate Restricted Work Schedules

In addition to seeking more time to accommodate family–work conflict, many workers need to decrease or have limited work hours to accommodate health or ability factors. Other workers are able to use less than full-time employment to transition into or out of the workplace. Job sharing can be an important option in both of these situations.

One population that is likely to benefit from the accommodation of flexible or reduced work hours is that of disabled workers. According to a 2003 report of the U.S. Census Bureau, approximately 18.5 million disabled Americans are employed, which is about 56% of all disabled people between 16 and 64 years of age. The U.S. federal government identifies job sharing as one of several strategies to accommodate employees with both psychiatric and physical disabilities. Employers have also indicated a willingness to consider job sharing in the hiring of people with disabilities.

Increasing unemployment rates in the late 1990s prompted some European countries to develop creative solutions to work transitions among older and younger workers. In Nordic countries, a system of job sharing was established to support phased retirements. Older workers cut down their weekly work hours, and new employees are hired in part-time positions to fill the remaining hours. In addition to providing employment opportunities to more workers, there is initial evidence that this strategy also provides some economic benefits.

### **Job Sharing as an Alternative to Employee Layoffs**

Several national and state governments recognize work sharing programs as a way of preserving employment for all (or at least more) workers during temporary decreases in productivity or economic downturns. Although these job share programs result in fewer hours for previously full-time employees, they generally do not reduce employee benefits. In addition, employees are frequently eligible to apply for unemployment insurance to compensate for the amount of hours reduced by the work share, although this is regulated by individual state and/or national governments. This kind of work share program differs from other job sharing arrangements in that it is typically monitored by government agencies and initiated by the employer, whereas other job sharing strategies are more often individually negotiated arrangements and most frequently initiated by the employee(s).

In a national evaluation of work share programs, Human Resources Development Canada found that an average of 10,302 (ranging from 2,264 in 1999–2000 to 32,524 in 1990–1991) layoffs were averted annually between 1990 and 2002 due to work share program participation. The International Labor Office identified several advantages and considerations for

both employers and employees in work share situations. For employers, advantages include greater ability to adjust to fluctuations in market demands and less time in retraining new employees when economic downturns reverse; disadvantages include the need to attend more carefully to employee scheduling and communication in order to avoid confusion and lowered productivity. For employees, advantages include job security; disadvantages include decreased wages.

### **Opportunities and Challenges**

Regardless of the specific nature of the arrangement, several advantages and opportunities are presented by job sharing. An important benefit of job sharing is the flexibility allowed the participants in the share. Assuming good communication and coordination of duties, job sharers are able to synchronize their schedules in a way that allows maximum productivity at work as well as adequate time to attend to other matters. Successful job sharing arrangements are likely to contribute to higher employee morale as well. Job sharing also allows employers to attract more talented employees and to organize work assignments to maximize individual worker skills. Job sharing also provides a way for employers to make work accessible to people who might otherwise be at a disadvantage.

Job sharing also brings with it several potential challenges. In situations in which two people are sharing a single job, good communication and complementary work skills are essential. Some overlap in hours is generally necessary, and this can reduce some of the flexibility that comes with the arrangement. Other employees might perceive job sharing employees as less involved or invested in the workplace, as might some supervisors. This could result in negative evaluation or lost opportunities, suggesting that organizations need to set up very clear expectations for job sharing employees so that everyone knows the criteria by which they are to be reviewed. Job sharing employees might themselves feel as if they need to put forth more time and effort, thus negating some of the benefits of the arrangement, reinforcing the need to have very clear expectations for all involved parties.

### **Future Directions**

Job sharing is one of several strategies for making the workplace more accessible and/or welcoming for workers with a diverse set of employment and personal needs. Further research is necessary to determine

how job sharing compares to other practices, such as compressed work weeks and flexible scheduling. In addition, claims that job sharing results in higher productivity and employee morale need to be further explored. Given that there is increasing interest in job sharing by both employees and employers, this area of vocational development warrants greater attention by scholars and clinicians in the counseling and psychology professions.

1993, the first issue was published. Walsh was the first editor of the journal. The main thrust of the journal is to publish methodologically sound, empirically based studies focused on the process and techniques by which counselors and others gain understanding of the individual faced with the necessity of making informed career decisions. The term *career assessment*, as used in this journal, covers various techniques, tests, inventories, rating scales, interview schedules, surveys, and direct observational methods used in scientifically based practice and research to provide an improved understanding of career decision making. The focus is not just testing, but all those means developed and used to assess and evaluate individuals, organizations, and environments in the field of career psychology, counseling, and development. *Assessment* is broadly defined to include the full range of assessment perspectives (objective, subjective, projective, behavioral, interactional, and developmental). A real strength of *JCA* is the focus on career assessment as it reflects the convergence of theory, research, and practice in diverse cultures throughout the world.

A change for the journal occurred in 2002. Sage Publications in Thousand Oaks, California, agreed to commence publication of *JCA* beginning with volume 10, issue 1, 2002. Since 1965, Sage has been devoted to publishing a number of journals in the fields of education and psychology. They are known for their flexibility, extensive worldwide marketing, proficient editing and production, and expertise in collaborating with professional organizations. It was a good fit for the journal.

The journal is abstracted or indexed in *Abstract Journal of the Educational Resources Center*, *Current Contents: Social & Behavioral Sciences*, *Current Index to Journals in Education*, *Psychological Abstracts*, *PsycINFO*, *Scopus*, and *Social Sciences Citation Index*. The *Social Sciences Citation Index* consistently ranks *JCA* among the top journals in the field of career psychology and assessment. The *Social Sciences Prestige Factor* also ranks *JCA* among the top journals in the field of counseling and vocational psychology.

Over the years the journal has published a number of special issues on topics such as career assessment for women, the assessment of interests, the use of personality inventories in career assessment, career assessment with racial and ethnic minorities, theory and career assessment, career assessment and the Internet, cognitive career assessment, qualitative career assessment, and career assessment and self-efficacy.

---

## JOURNAL OF CAREER ASSESSMENT

---

The concept for the *Journal of Career Assessment* (*JCA*) was developed in 1989 by W. Bruce Walsh of Ohio State University. On June 7, 1991, Robert Smith of Psychological Assessment Resources accepted the proposal to become the publisher of *JCA*. In January

The journal continues to be published 4 times a year with an average of 125 pages per issue. The editorial board consists of about 25 professional counseling psychologists. A blind review process is used to evaluate manuscripts.

## JOURNAL OF CAREER DEVELOPMENT

---

The first issue of the *Journal of Career Development* (vol. 1, no. 1) was published in the fall of 1972 under the title *Journal of Career Education*. The following statement of purpose appeared in the first issue:

This publication will endeavor to support and summarize the thrust of current trends in career education, with a special focus on the integrated approach to vocational and technical education. This will be done by documenting in journal form efforts which signify exemplary leadership in promoting these concepts.

The next issue of the *Journal of Career Education* (vol. 1, no. 2) did not appear until the fall of 1974. H. C. Kazanas served as editor. From then on the journal has been published quarterly. In the fall of 1978, Norman C. Gysbers was appointed editor beginning with volume 5, number 1. At that time it became an official publication of the College of Education, University of Missouri–Columbia. Copyright was held by the Curators of the University.

A major change for the journal occurred in 1984. The name was changed to the *Journal of Career Development*. The reason the name was changed was the need to broaden the purpose, scope, and content of the journal beyond K–12 education to focus on the life span, early childhood through the adult years. The

new purpose emphasized journal content that featured career development theory, research, and practice covering such topics as adult career development, the career development of special needs populations, career development and the family, career development in organizations, and career and leisure.

From 1972 until 1985, the journal was published and marketed in-house on the campus of the University of Missouri–Columbia. When Gysbers became editor in 1978, a fully operational editorial board was put into place and the use of blind reviews. Also, during this time period, extensive efforts were made to increase subscriptions, particularly library subscriptions, using subscription agencies.

In 1985, the editor, in consultation with the University of Missouri officials, made the decision to respond to a proposal from Human Sciences Press to assume the task of publishing and marketing the journal. A contract was signed in 1985. As a result, the first issue published under this new arrangement was the fall 1985 issue, volume 13, number 1. What had been an in-house publishing and marketing operation became a professionally published and marketed journal. The authority to appoint editors and editorial board members and to decide on editorial policy remained with the University of Missouri–Columbia.

The contract to publish the *Journal of Career Development* with Human Sciences Press (now Springer) remained in effect through volume 31, number 4. In 2004, the University of Missouri–Columbia signed a contract with Sage Publications to publish and market the journal. The first issue published by Sage was volume 32, number 1, 2005. In another change, Lisa Flores became the editor beginning with volume 33, number 1.

## JOURNAL OF VOCATIONAL BEHAVIOR

---

The *Journal of Vocational Behavior* (*JVB*) publishes empirical, methodological, and theoretical articles that expand knowledge about vocational choice and work adjustment across the life span. Studies of vocational choice typically examine topics such as career choice; occupational interests; the relation of abilities, needs, values, interests, and personality to occupational aspirations and the career decision-making process; vocational development tasks and career stages; the effects of culture, demographic variables, and experiential factors on career decision making and occupational attainment; career indecision and vocational maturity; occupational stereotyping; and career exploration and job search. Studies of work adjustment typically investigate topics such as job performance and success; job satisfaction; mentoring; work adjustment; organizational commitment and job involvement; work–family relations and multiple role management; work–leisure relations; midlife career change; occupational reentry; and transitions from work to retirement. *JVB* also publishes articles about career interventions and conceptual articles that address career theory. Psychometric research is also represented, particularly manuscripts that report the construction and initial validation of new instruments, but also studies that evaluate the reliability and validity of widely used instruments that measure central concepts in vocational choice and work adjustment. Articles that report meta-analyses and research integration of the topics noted above are highlighted in the journal.

*JVB*'s distinctiveness arises from its emphasis on publishing research that deals with vocational behavior from the perspective of the individual rather than the perspective of the organization. Studies of organizational behavior and of variables more highly related to the welfare of organizations than to the individual ordinarily do not appear in *JVB*. Thus, *JVB* does not publish research on organizational topics such as leadership or management. Intermittently, the journal publishes special issues that explore a single topic in depth. Often these special issues relate to significant anniversaries in the field of vocational psychology such as the 40th anniversary of John L. Holland's theory of vocational personalities and work environments

(August 1999) and the 30th anniversary of *JVB*'s founding (October 2001). Special issues are also used to highlight emerging perspectives and to assemble articles on a single topic. Recent special issues have addressed technology and careers, careers in academe, social constructionism, career specialty choice, and longitudinal studies of development in context. The list of most-downloaded articles reflects strong interest in the topics of emotional intelligence, person–organizational fit, work–family relations, organizational commitment, mentoring, career success, and career decision making.

*JVB* was founded in 1971 by Samuel H. Osipow, then a professor of psychology at Ohio State University who sought an outlet for research on vocational psychology. Osipow has been succeeded by Lenore W. Harmon, Nancy E. Betz, Howard E. A. Tinsley, and since 1999 Mark L. Savickas. *JVB* publishes 1200 pages each calendar year in the form of six issues divided equally into two volumes. Originally published by Academic Press, *JVB* is now published by Elsevier. Abstracts and the full text of all articles published in volumes 1–70 are available on Science Direct.

## KRUMBOLTZ, JOHN D. (1928– )

---

John D. Krumboltz, Ph.D., has demonstrated throughout his life and work that counselors can help clients with career, academic, and personal problems to explore and expand their learning experiences; challenge unhelpful beliefs; embrace unanticipated opportunities; and take positive actions to create more satisfying lives for themselves. He received from the American Psychological Association the Award for Distinguished Professional Contributions to Knowledge (2002) and the Leona Tyler Award (1990), the nation's foremost award in the field of counseling psychology. A leading theorist in career development, in 1979 Krumboltz proposed a social learning theory of career decision making. In 1996, he expanded this into a learning theory of career counseling and has since added the concept of planned happenstance.

Krumboltz views career indecision as a consequence of ineffective learning (e.g., unsatisfactory or insufficient learning experiences). He maintains that the role of career counselors is to use career assessment tools and cognitive-behavioral counseling methods to help clients expand their learning about current and potential interests, skills, values, beliefs, personal qualities, and work habits. To progress beyond the counseling goal of insight, Krumboltz developed the Career Beliefs Inventory and a workbook titled *Exploring Your Career Beliefs* to help clients not only think and talk about their assumptions that might facilitate or impede their career development, but also take action to test out these assumptions and learn more helpful behaviors.

Furthermore, in order to create a satisfying life in the context of a constantly changing work environment, Krumboltz posits that career counselors can teach their clients to generate and transform unplanned events into opportunities for learning. He notes that unanticipated events attributed to luck are often a result, at least in part, of effective behavior that can be taught. Although the concept of planned happenstance pairs seemingly contradictory terms (i.e., how does one plan for chance events?), Krumboltz suggests that clients can learn to act in ways that maximize the frequency of beneficial chance events as well as plan to be receptive to and capitalize on chance opportunities.

Readily admitting that his own career path was not totally the result of rational planning, Krumboltz has shared that he was undecided in selecting an undergraduate major when he attended Coe College. He had explored one option (economics) that he learned was not satisfying for him. When the coach of his varsity tennis team, who also happened to be a professor of psychology, suggested that he major in psychology, Krumboltz did so. Since then, he has capitalized on this chance opportunity to expand his learning in psychology, explore fascinating questions in counseling psychology and career development, and make significant contributions to the science and practice of counseling.

After earning a bachelor's degree in psychology from Coe College and a master's degree in guidance from Teachers College, Columbia University, Krumboltz worked as a high school counselor and taught algebra in Waterloo, Iowa. Dissatisfied with the nondirective counseling approach that he had been taught to apply and seeking more scientific and practical

methods, he obtained a Ph.D. in counseling and educational psychology from the University of Minnesota. Then he served as a research psychologist when called to active duty in the Air Force. He continued to pursue his interest in behavioral psychology as an assistant professor at Michigan State University. At Stanford University since 1961 and currently a professor of education and psychology, Krumboltz has served as a revolutionary role model for lifelong, challenging, and positive learning.

## KRUMBOLTZ HAPPENSTANCE LEARNING THEORY

---

A theory is simply an explanation for understanding how things happen and why. A learning theory about career development explains how people discover their current occupations through a variety of different learning experiences. Within the learning theory framework, how occupations—accountant, senator, plumber—developed from life's learning experiences can be explained. Our society advocates that people plan and declare an occupational goal early in life. A common question asked of children is, "What do you

want to be when you grow up?" Paradoxically, very few adults are doing exactly what they planned at age 18. Unplanned events play a major role in everyone's career development. If serendipity is included as a crucial part of the learning process, we have what can be called a *happenstance learning theory*.

Throughout life people have innumerable learning experiences. Every minute people are engaged in learning activities whether they know it or not. Some experiences are planned, many are not. Every time a person talks to another person, he or she learns something. Every time a person watches TV, listens to the radio, or plays a game, he or she learns something. The happenstance learning theory categorizes learning experiences into two major categories: *instrumental* and *associative*.

Instrumental learning experiences are those in which people take some action and observe the consequences. For example, if a child is playing a game of baseball, comes up to bat, and hits well enough to get on base, the child has succeeded in an activity and has positive feelings as a result. Another child may come to bat and be unable to hit the ball at all, striking out. The happenstance learning theory posits that it is more likely that the first child would develop greater aspirations for a baseball career than the second child. The more children actively engage in activities, the more likely they are to encounter valuable learning experiences. Every time people do something—that is, engage actively—they find out what happens as a result and discover how they feel about it.

All instrumental learning experiences take place in a cultural and opportunity context. Baseball is a popular sport in the United States. Cricket is popular in England and India. In some other countries both sports are virtually unknown. The environment in which one is born and raised provides only certain types of learning opportunities.

Associative learning experiences occur as people watch, listen to, or read about others. For example, listening to a rock concert might inspire some people to become a rock singer. Reading about a science experiment might inspire some people to train to become chemists or biologists. Watching a carpenter at work may inspire others to discover the glories of wood working.

All of these associative learning experiences also depend on cultural context. For example, the opportunity to read about a scientist's experience depends on access to books. Some people live far from the nearest public library. Some families subscribe to magazines

and newspapers that children might spontaneously browse; other families may not. Some parents read to their children at a young age, opening a world of imagination and early literacy; other parents may not.

As a result of these continuous learning experiences, people form generalizations about their own interests, abilities, values, and beliefs. Some experiences might generate memorable interests and passions; others may not. People tend to gravitate naturally toward activities that yield emotional, social, and financial benefits. They tend to avoid activities that are distasteful and yield few benefits. Over time these tendencies lead people to engage in various types of occupations. For example, if through skillful instruction, often in a problem-based learning style, some children learn the fun of working with numbers, they might be more likely to gravitate toward occupations like accounting. Other children, enduring inadequate pedagogy in schools, might come to fear mathematics and gravitate far away from occupations that involve manipulation of numbers.

Innumerable unplanned events influence the experiences of each child. There is no way to know in advance what experiences a child might stumble across and what the consequences will be. However, it is known that the more a child is encouraged to be curious, to take risks, and to engage actively in learning opportunities, the more valuable the learning is likely to be. Learning occurs whether the opportunity is planned or unplanned. Children benefit from having multiple opportunities to observe others and to engage themselves in a variety of tasks and activities.

There is sometimes a misunderstanding that the word *happenstance* means that luck will occur if one waits passively for something to happen. That is far from the truth. One increases the probability of a happenstance event occurring by engaging in new activities. If one does nothing, nothing happens.

Sometimes people are told that they should complete their education. The happenstance learning theory advocates that one should never complete an education. People should continue learning throughout life. People can create their own luck by putting themselves in environments in which they can try activities and learn from them. People can change their occupational endeavors at any time in their life. Now, most people change career direction a number of times over their lifetimes. There are many advantages to keeping one's options open through active engagement in new experiences.

One no longer has to answer the question, "What are you going to be when you grow up?" Since one never knows what opportunities may be just around the bend, one can now respond, "I'm open and prepared for whatever is down the road." Contemporary career advice encourages people to keep an eye open for opportunities and to follow up on opportunities when the time is right. Past experience is not investment that must be continued when it is no longer satisfying. Remaining open to opportunities provides a better strategy for creating a satisfying life.

In the 1990s, "follow your bliss" became a well-known phrase in the popular career literature and was promoted as the secret to pursuing satisfying career and life experiences. However, under this premise those without a defined passion are left adrift. Passions are learned. When people do something that they enjoy and think it is important, they develop a passion for it. Through active engagement in new experiences, one learns what activities resonate personally as interesting, fun, and worthwhile. No one is born knowing that they will become a passionate singer. People who listen to others sing, begin singing themselves, and find it inspiring may well develop a passion for singing. However, one has to engage in singing first in order to develop a passion for it.

The happenstance learning theory has roots in behavioral psychology, ties to emotion theory, and moves in the direction of positive psychology in terms of resilience and adaptation to a rapidly changing world. The emphasis is on perpetual openness to new opportunities over a lifetime.

Work in the 21st century is destined to be a tremendous adventure, dynamic, fluid, and global, with a level of variety over the life span that could have never been imagined in prior centuries. Successful people will demonstrate a certain occupational resiliency characterized by flexibility, optimism, lifelong learning, daily networking, and a clever eye for opportunity. The happenstance learning theory explains how a lifetime of active involvement provides learning opportunities that may have been planned or unplanned. It is neither possible nor desirable to predict exactly what people will be when they grow up. The process continues throughout life, so people need to keep their options open at all times. Perhaps it is therefore more productive to ask children, "What are you enjoying and learning to do right now? What would be fun to try next?"

## KUDER, FREDERIC (1903–2000)

---

Frederic (Fritz) Kuder is best known as the author of the Kuder Preference Records, four distinctly different forms of an interest inventory that since their introduction in 1938 have been taken by millions of people worldwide.

As a transfer student at the University of Arizona, Kuder came late to a required orientation meeting for new students and was seated next to another late-comer, a son of James McKeen Cattell, with whom he became a close friend. Cattell—who is credited with introducing mental measurements in the United States and later with the founding of the Psychological Corporation—at the time led Science Press, a company that published *American Men of Science*. After Kuder graduated with his degree in English, this

association led to a job as an editorial assistant at Science Press. Kuder was interested in vocational guidance and earned a master's degree at the University of Michigan under George E. Meyers, who was an early president of the National Vocational Guidance Association, now National Career Development Association.

After a period of employment in the personnel department of Procter & Gamble Company, where he worked on selecting sales personnel, Kuder continued his studies at Ohio State University under Herbert Toops, who was known for the development of a college entrance examination, Ohio State Psychological Examination. Several of Kuder's publications from this era concerned test development and the use of the IBM tabulating machines to perform statistical computations.

With his doctoral degree completed, Kuder went next to the University of Chicago, where he worked under the direction of L. L. Thurstone preparing placement and comprehensive exams for students. Here he began work on the Kuder Preference Record—Vocational, an interest inventory unique for using a triad of activities from which the inventory taker selected the most and least preferred activities. It was first scored for 8 and later 10 kinds of interests, which he developed with statistical techniques not unlike factor analysis, all using hand and electrically operated computation machines. He also developed a personality inventory for use in personnel selection, which enjoyed some popularity in the post–World War II years. These inventories became well known among test takers as the pin punch tests, owing to the scoring system that required that responses to items be punched into an answer pad with a pin, facilitating scoring by clerks or the inventory takers themselves.

After employment during the World War II years with the federal government, Kuder taught statistics at Duke University, where he developed his Occupational Preference record, which yielded scores reflecting the inventory taker's similarity with individuals in a variety of occupations.

In 1977, Kuder published a paper advancing a new concept of vocational assessment, which instead of matching the inventory takers with groups of people in various occupations, matched them with individuals in a wide range of occupations, and more specifically in a variety of careers. Now available exclusively online, Kuder Career Search in its first decade of

publication had been taken by more people than by those who took the previous Kuder inventories in their first 60 years.

Kuder was, with John G. Darley and E. G. Williamson, one of the founding members of the Division of Counseling Psychology of the American Psychological Association and was the group's second president. Kuder founded and was editor for a long period of *Educational and Psychological Measurement* and cofounded *Personnel Psychology*. He received the award for distinguished service to measurement from Educational Testing Service and is listed in the book he once helped produce, *American Men and Women of Science*. He was one of the several prominent 20th century psychometricians who brought psychological testing to its present high state. But in the years before his death, he liked to say that he mainly tried to help young people find satisfying careers.

## KUDER CAREER SEARCH

---

Kuder Career Search (KCS) represents the third generation of interest inventories known as the Kuder Preference Records. First was the Kuder Preference Record—Vocational, which gave scores on 10 vocational interest scales. Next was the Occupational, which reported occupations that were similar to the inventory takers' interests.

The KCS consists of two kinds of scales. One, the Kuder Career Clusters, reveals the similarity of the inventory taker's activity preferences to those of people in certain clusters of occupations. The unique second score gives Person Matches, which reflects the similarity of the inventory taker's interest profile to each person in a pool of some 2,000 employed adults.

Available only online at [www.kuder.com](http://www.kuder.com), the KCS is suitable for middle and high school students, 2- and 4-year college students, and adults. Individual purchases are available, but the inventory is typically administered in school as part of a career development program. The reading level is approximately sixth grade, and administration time averages 15 to 20 minutes. The inventory consists of 60 triads of activities: draw sketches of birds, build boats, sort mail in a post office, and so on, which the respondent rank-orders by preference. Scoring is instantaneous with the last response, and an online report yields a profile of cluster scores plus the job titles of the top 12 Person Matches.

Supporting materials for the KCS include two other assessments, the Kuder Skills Assessment, in both school and college or adult levels and the Super's Work Values Inventory, occupational and college information, a portfolio that can be made to generate a college or job application and an administrator's management system.

The KCS report emphasizes ranks, not scores. Mature users who are motivated to study their results and seek further information may use their results independently. High school and middle school students, especially those who are little motivated to consider their future careers, will benefit from competent attention.

The materials lend themselves to both individual and group applications. They may be used in individual counseling, in school settings as a component of an ongoing advising or career development program, or as an instructional unit in the regular classroom. Individual or small group interpretation may facilitate students in identifying diverse ways of realizing an occupational goal, such as nursing, teaching nursing, or becoming a nursing administrator.

Lower reliabilities for interest measurement at middle school ages suggest that the KCS is best used to develop or clarify an occupational self-concept or to prioritize several possible career paths. In high school, the KCS supports more refined career exploration such as making plans for a college major and selecting valid occupational possibilities. At the college level, the inventory may be used with individuals who have not chosen a major field of study or with those who need to replace an unsatisfactory choice. Among adults, the KCS may suggest career possibilities to replace a lost job or to suggest more satisfying occupational roles.

## Kuder Career Clusters

Kuder Career Cluster scales may appear on the surface to be homogeneous types of interest scales. In fact, they are criterion group scales formed from clusters of related occupations from a pool of employed adults, roughly representing the breadth of career opportunities in the United States. The KCS is scored for six clusters, corresponding to the well-known Big Six interest dimensions: Outdoor/Mechanical, Science/Technical, Arts/Communication, Social/Personal Services, Sales/Management, and Business Operations. Scales customized to other schema, such as the States' 16 Clusters, have been constructed as well. Clusters are presented on-screen in rank order of their percentile scores, based on a general norm group of 8,791 males and females from middle school to adult. It is suggested that users give primary consideration to their top two ranking clusters.

## Person Match

Person Match compares the activity preference profile of the inventory taker with those of each of the individuals in the Person-Match Pool and selects by means of correlational analysis the individuals who are most similar. The yield may be of persons all in the same occupational field, although with differing job titles, or it may consist of individuals in several occupations. Nevertheless, all of the people involved, the interest inventory taker and the person matches, all have relatively similar reported interests.

## Job Sketches

If a person's similarity to another person is the fundamental information yielded by the KCS, that information must be more fully developed than a simple job title. Thus, inventory takers are provided with job sketches of their top matches. In general, these sketches offer a first-person account of what the individual does at work, sources of satisfaction and dissatisfaction, previous occupations, and plans for the future. The job sketches are far from uniform, emphasizing aspects that have personal meaning to the incumbent and presumably engaging the interest of the inventory taker in the possibility of the represented career.

Although no empirical test of the utility of job sketches compared to occupational titles from other interest assessments has been undertaken, their potential value is underscored by the proliferation of books offering interview materials with satisfied workers.

The text of the report for the KCS contains many links to information that elaborates the content of the on-screen report. Users may click on any cluster to obtain a definition of that cluster or click on any job title to open the corresponding entry in the *Occupational Outlook Handbook*, which offers additional information such as income levels, the employment outlook, and links to college majors, financial aid, and the like.

Further technical details and psychometrics of the KCS are available in the user manual available at [www.Kuder.com](http://www.Kuder.com).

## Interpretation

Users of interest inventories often are heard to say, "The test says I should be a . . . ." In the case of the KCS, the test says two things, but never as a *should*. One is activity preferences, which might be best represented as, "Your top preference appears to be (name of highest-ranking Kuder cluster), and your next preference is (name of second-ranking cluster)." The other concerns person matches, about which the counselor may say, "You have interests like those of . . ." naming several job titles (all of which may or may not be in the same occupation) and "You really can learn a lot about yourself by giving their job sketches a reading." Emphasis should always be given to the theme, "These people like the same things you like; they are similar to you," and followed up, "Why don't you see what else you can find out about their careers?"

## LIFE-ROLE BALANCE

---

Life-role balance refers to the construction of a desired life structure that reflects a person's own definition of a balanced life. Work occurs within a person's overall life structure, and addressing this basic fact in career theory and practice fosters life-role integration or balance. Helping clients clarify their desired life structure and empowering clients to move toward life-role participation that reflects their definition of a balanced life is an increasingly important component of the career intervention process. When career practitioners help clients examine how their involvement in multiple life roles provides a sense of meaning and identity, they provide holistic career assistance that reflects life as people live it and increases the probability of living a life in balance.

### Challenges to Life-Role Balance

Changes in the nature of work, the influence of technology, demands created by dual-career parenting or single parenting, and lifelong learning requirements represent some of the challenges confronting contemporary workers. Workers today also work longer and earn less than their counterparts did several decades ago. Many workers experience heightened anxiety about the prospect of being laid off from work as record downsizing occurs throughout the world. Technological advances also displace many workers and often make it necessary to work more hours.

These are not benign challenges confronting adults. For example, in Japan the second leading

cause of death, after cancer, is referred to as *karoshi*, which is defined as death from overwork. Overwork is not gender biased. Many women report a lack of family time as their greatest concern. Many dual-career parents experience conflict trying to find time to express their work and family commitments. The stress associated with such conflict often creates marital tension with negative outcomes for family systems. Managing decisions about life-role participation can become overwhelmingly complex in the face of such challenges.

Unfortunately, career practitioners and theorists tend to operate as if lives are lived in compartmentalized silos. Choices regarding work are conceptualized as if they occur in isolation from other domains in a person's life. This approach represents a false scenario and is ineffective practically and theoretically. It fosters life-role conflict rather than life-role integration and balance.

### Acknowledging Life-Role Interactions in Career Development

When practitioners and theorists acknowledge the challenges to achieving a balanced life, they begin to approach career as it is lived. They link career development with human development and embrace the fact that there are few things more personal than a career choice. This fact raises an important point concerning life-role balance: defining a balanced life occurs at the level of the individual.

Defining what constitutes a balanced life, or a satisfying life structure, requires substantial self-awareness. Being aware of which life roles are important and

which are peripheral helps to prioritize time and commitments. It is essential to effective time management, which is a core skill related to achieving a balanced life.

Knowing which life roles are important in the present, however, is insufficient. Knowing which life roles will be important in the future helps guide the planning behavior of children and adolescents. Because life-role self-concepts evolve over time, adults must also maintain a high level of self-awareness pertaining to which life roles are most salient in the present and which are likely to be most salient in the future.

Thus, a prerequisite to achieving life-role balance is developing crystallized life-role identities. The crystallization process commences with the beginning of life as infants are exposed to multiple learning experiences (e.g., having nurturing parents vs. less nurturing parents, engaging in enjoyable leisure activities, experiencing success as a learner) and continues throughout life as adult life-role identities evolve.

People are exposed to life-role models in the home, community, school, and workplace. The accumulation of life-role experiences leads to general life-role beliefs (e.g., “lifelong learning is essential”) and self-referent life-role beliefs (e.g., “I enjoy participating in competitive team sports”). These cumulative learning experiences reflect numerous interactions between the person and the environment and shape four significant aspects of life-role identity development. Specifically, these are (1) role expectations, (2) role conceptions, (3) role acceptance, and (4) role performance.

Role expectations are the historical and cultural prescriptions that are generally assigned to a role (e.g., the role of *worker* in the United States in the 1800s was defined very differently than it is defined today in the United States). Role conceptions involve the way in which people actually perceive or interpret the role-related expectations (e.g., to be a “good” parent, I need to be a good provider, behave in a nurturing way to my children, and be fair and consistent in disciplining my children). At times, people can inherit, from society and/or from the family, role conceptions that can become dysfunctional (e.g., “I would love to be a stay-at-home father, but that is not a role that is acceptable for men”). Role acceptance involves the willingness of the individual to become involved in the role. Role performance involves the actual behavior of the individual in the role situation. Collectively, these aspects of life-role identity

development influence whether a person moves toward or away from participating in a specific life role and guide the person in constructing a balanced life structure. Understanding a person’s life-role beliefs fosters a deeper understanding of a person’s motivation, goals, and obstacles relative to life-role behavior and life-role balance.

In this sense, it is important to note that life roles are enacted rather than occupied because life roles reflect interactions among personal determinants, situational determinants, and societal expectations as well as the individual’s expression of those expectations. Occupying a role suggests that roles are fixed positions that are stagnant and rigid, a description that is not the case. Two individuals can enact the same life role differently because of their unique contexts. Finding outlets for expressing one’s life-role self-concepts is essential for experiencing satisfaction in life. Although temporary departures from what the individual defines as a balanced life are normative, extended deviations are problematic. Thus, managing one’s life structure in a way that is consistent with one’s values becomes an essential career development task for career and life satisfaction.

### **Career Interventions to Address Life-Role Identity Development**

Career interventions that address life-role identity emerge from the work of Donald Super. Values clarification activities provide a starting point for achieving an acceptable level of life-role balance. Beyond values assessment, Super used the life career rainbow to help clients examine their life-role behavior in the past, present, and future. Individuals can use the rainbow to plot their previous and current life-role activities. They can discuss the values they seek to express in each life role and their level of satisfaction with their current life-role activities. Future scenarios can also be clarified as individuals identify future life roles they hope to participate in and the values they hope to express in those life roles. The rainbow also highlights the fact that various personal (e.g., values, needs, and interests) and situational determinants (e.g., community, school, and social policies) influence when and how people play particular life roles.

Constructing a family genogram can be a useful strategy for exploring the interaction between family background, cultural prescriptions, and career planning. The family genogram provides the opportunity

to focus on the career and life-role beliefs passed down through the generations. This information can also be used to contrast influences on life-role salience emanating from group-oriented cultures with influences from more individualistic cultures. The effects of sex-role stereotyping on life-role salience can also be examined in these discussions. The goal of this intervention is to increase awareness as to the factors influencing peoples' beliefs about the primary roles of life.

Career practitioners can also help their clients explore life-role participation by encouraging them to consider questions such as the following: How do I spend my time during a typical week? How important are the different roles of life to me? What do I hope to accomplish in each of the life roles that will be important to me in the future? What do my family members expect me to accomplish in each life role? Answers to these questions help clients consider behavioral, affective, and cognitive dimensions of life-role behavior.

Collectively, these interventions help clients acquire an understanding of their life structure. This understanding then becomes the catalyst for constructing a desired life structure that increases the probability of living a balanced life as each person defines it.

## LOFQUIST, LLOYD HENRY (1917–1996)

Lloyd Henry Lofquist was more than the prototypical University of Minnesota–trained psychologist—he devoted the greater part of his life to the university and to the field of counseling psychology. Born in Minneapolis in 1917 into a tradesman's family, Lofquist spent his entire life in the Minneapolis–St. Paul, Minnesota, area, except for the period 1942–1946 when he was abroad in the military where he earned the rank of captain and a bronze star. For 2 of those years, 1943–1945, Lofquist was a psychologist in the Personnel Branch of the U.S. Army's Adjutant General's Office and applied the counseling and personnel skills he had learned while completing his master's degree in 1941 at the University of Minnesota, one year after completing his B.A., also at Minnesota.

When Lofquist returned from World War II, he took a position as Counseling Psychologist at the Minneapolis Veterans Administration hospital, where he rose to become its chief while at the same time completing his Ph.D. at Minnesota in 1955. In that year, his graduate adviser, Donald G. Paterson, the architect of applied psychology, recruited Lofquist to return to the Minnesota Psychology Department to become the head of its new Counseling Psychology Program, which focused on vocational rehabilitation counseling and vocational psychology.

Shortly after Lofquist arrived back at his alma mater, he secured a 2-year research grant from the then U.S. Office of Vocational Rehabilitation for a follow-up study of rehabilitation counselees, which then resulted in funding the Work Adjustment Project from 1959 through 1972. It was this project, in conjunction with working with his colleagues George W. England, René V. Dawis, and David J. Weiss that gave rise to the theory of work adjustment and to an empirical research program that lasted 30 years.

Lofquist's research productivity, all focused on vocational psychology and work adjustment, consisted of 15 published journal articles, five books, and 49 book chapters and research monographs. While on the University of Minnesota faculty, from which he retired in 1989, Lofquist served as the Co-Principal Investigator of the Work Adjustment Project for its entire existence and as the first Director of the Counseling Psychology Program; at the same time, Lofquist was also responsible for beginning and

managing for many years the Department's Rehabilitation Counseling Graduate Student Training Grant and for founding (with René V. Dawis) the University's Vocational Assessment Clinic, which today still provides vocational counseling services based on the theory of work adjustment to Minnesota residents.

Like many Minnesota-trained psychologists, Lofquist's professional activities included a balance of theory, research, and applications. In addition to these professional accomplishments, Lofquist found time to serve the university as well—he was Associate Dean of the College of Liberal Arts from 1967–1970, Associate Vice President for Academic Affairs from 1970–1973, and Chair of the Department of Psychology from 1975–1985. His contributions to the field of vocational psychology, through the theory of work adjustment and the research and instruments that it spawned, continue to influence the field through his many former graduate students, their students, and future generations of students.

## MINNESOTA IMPORTANCE QUESTIONNAIRE

---

The Minnesota Importance Questionnaire (MIQ) is a measure of work needs and work values. Work needs are a person's requirements for satisfaction in work. Job satisfaction results when the conditions in work (work reinforcers) correspond to one's work needs.

The MIQ measures work needs by asking the person how important the following 20 work reinforcers are to one's job satisfaction: ability utilization, achievement, activity, advancement, authority, company policies and practices, compensation, coworkers, creativity, independence, moral values, recognition, responsibility, security, social service, social status, supervision—human relations, supervision—technical, variety, and independence.

Work values are basic dimensions of what is important to the person. Work values underlie work needs and are measured from them. The MIQ measures these six work values:

1. achievement—the importance of using one's abilities and having a sense of accomplishment;
2. altruism—the importance of harmony with, and being of service to, others;
3. autonomy—the importance of being independent and being in control;
4. comfort—the importance of being comfortable and avoiding distress;

5. safety—the importance of predictability, stability, and order; and
6. status—the importance of recognition, prestige, and being important.

The MIQ is a self-report questionnaire that is available in two forms. In the Paired Form, each need is paired with every other need, and the respondent picks the need in each pair that is the more important. Most respondents complete this form in 30 to 40 minutes. In the Ranked Form, needs are presented in blocks of five, and the respondent rank orders the five needs within each block according to importance. This form requires a 21st need: autonomy. This form is usually completed in 15 to 25 minutes.

The MIQ is appropriate for persons who read at the fifth-grade level or higher. Test materials and manuals are available from the MIQ's publisher, Vocational Psychology Research, University of Minnesota. The *MIQ Manual* provides information needed for test administration, score interpretation, and counseling use of the MIQ. A more technical manual that details the research about the development of the MIQ is also available. A Spanish-language MIQ is available.

Scoring services are provided by Vocational Psychology Research. The MIQ Report lists the respondent's need and value scores and presents the scores in a profile. A validity score—consistency of response—is included.

The MIQ Report also details how well the respondent's work needs correspond to the work reinforcers present in various occupations as estimated by

supervisors or incumbents in these occupations. The Standard MIQ Report gives correspondence information for 90 benchmark occupations representative of the full occupational range. The Extended MIQ Report provides the same information for 185 occupations. For each occupation, a prediction is made of the likelihood that the respondent will be satisfied in the occupation.

## MULTICULTURAL CAREER ASSESSMENT MODELS

---

Career assessment involves an ongoing process of gathering information to assist clients to make career-related decisions. Useful information to gather in career assessment includes but is not limited to understanding a person's personality, values, skills, interests, life roles, and career history. Assessment information is typically gathered via intake interviews, standardized tests and inventories, and non-standardized methods such as card sorts, career genograms, and career lifelines. The data that are obtained can be used to inform both the career counselor and the client and to help set appropriate goals and strategies for achieving the goals in career counseling. Multicultural career assessment incorporates information about the client's cultural background such as race, ethnicity, gender, social class, and sexual orientation and uses this information to understand how these factors may have shaped one's career development. In essence, in contrast with traditional career assessment, the cornerstone of multicultural career assessment is understanding a person's career issues within a cultural context.

Recent advancements in area of career assessment with culturally diverse groups are apparent in the growth of multicultural career counseling models and multicultural career assessment models that have been formulated. An integral element to effective career counseling with culturally diverse individuals includes accurate and valid career assessment. Several models and frameworks have been developed to guide the career assessment process and to understand the career needs of culturally diverse individuals. Some of these models, which are described below, have focused solely on assessment, while others have attended to assessment issues within the context of career counseling with culturally diverse clients.

### Healy's Career Appraisal Model

Healy's model served as one of the early forerunners of career counseling models that incorporated cultural variables. Healy criticized traditional career models for the hierarchical counselor–client relationship and the lack of emphasis on environmental barriers in the implementation of career goals. As an alternative to the traditional approaches, Healy proposed a reformed career appraisal model that explicitly recognized contextual issues. Furthermore, this model advocated for collaboration with clients, empowerment of clients to take an active role in their career development, and follow-up with clients to help them implement goals.

### Career Assessment Models for African American Clients

In this model from Swanson and Bowman, four steps for tasks and decisions for the career assessment of African Americans were outlined. The four steps include establishing rapport, choosing a formal assessment process, determining the type of assessment and assessment instrument, and providing an effective test interpretation by emphasizing the counselor's experience.

### Career Assessment Models for Racial/Ethnic Minority Women

Feminist theories highlight the importance of understanding the impact of sexism and the oppression of women's lives. These feminist tenets have served as a foundation for the development of career assessment

models for women of color, whereby the influence of gender socialization and social barriers in the career development of women are emphasized and acknowledged. One approach to career assessment by Forrest and Brooks identifies four important aspects of this process that are grounded in feminist ideology. First, the client and the counselor are considered equal. Second, an awareness of sociocultural conditions that have limited women's experiences and opportunities is critical, and these factors contribute to women's career problems. Third, women must understand how these career problems affect their own social, economic, and political environment. Finally, the goal of feminist therapy is to enable women to be independent, which is essential for their mental health.

Feminist writers have also emphasized the role of client-generated information in counseling. Ward and Bingham offered a framework for the career assessment of ethnic minority women using the clinical interview as the primary assessment tool. They recommended that the career counselor do additional preparation before encountering a diverse client and needs to continuously work on establishing rapport throughout counseling. In addition, counselors should assess the impact of the culture, family influences, racial/ethnic issues, and finances of the client that are presenting concerns. The counselor may prepare for working with culturally diverse clients by using the Multicultural Career Counseling Checklist for Counselors, which was designed to encourage counselors to assess personal multicultural counseling competencies.

Later, Bingham and Ward incorporated the assessment of self-efficacy variables in addition to general cultural variables such as worldviews and structure of opportunity and gender variables as important areas of assessment with women of color. Incorporating this information with data obtained through traditional career assessment variables, such as career interests and work values, comprises the core components of Bingham and Ward's career assessment model.

### **Culturally Appropriate Career Counseling Model**

Fouad and Bingham developed the culturally appropriate career counseling model (CACCM) because mainstream theories did not mention cultural factors and offered minimal attention to factors related to career assessment with racial/ethnic minorities. The

assessment component of the model proposes the appraisal of five spheres that affect career issues, including the individual, gender, family, racial or ethnic group, and dominant group. Relevant constructs within each sphere that are expected to influence career should be evaluated. For example, personality, gender roles, family expectations, cultural values, and structural barriers are variables that may be considered for each of the respective spheres. This model is unique because it incorporates culture into every phase of the career counseling process, including career assessment. Assessing how multiple factors may affect the career self-efficacy, interests, options, and decision making of culturally diverse individuals is important because each of these realms is believed to have unique effects on individual career choices.

Recently, the concept of metacognitive awareness was integrated to the CACCM to explicitly address the counselor's cultural context. Specifically, active engagement in a self-reflective process, or metacognition, is believed to help counselors to maximize their ability to evaluate and address personal cultural backgrounds when working with culturally diverse clients.

### **Integrative-Sequential Framework**

This framework by Leong and Hartung includes five stages for assessing career concerns: (1) the emergence of career and vocational problems, (2) help-seeking and career service utilization behaviors, (3) evaluation of career and vocational problems, (4) career interventions, and (5) outcomes of career interventions. This model is distinct from prior frameworks because it includes defining the client's problem in a cultured context; and by doing so, it highlights the transition from identifying the problem to utilizing career counseling services.

### **Culturally Appropriate Career Assessment Model**

The culturally appropriate career assessment model, developed by Flores, Spanierman, and Obasi, consists of four interrelated steps for evaluating career clients: gathering culturally encompassing information, selecting culturally appropriate career assessment instruments, administering culturally sensitive instruments, and interpreting data in a culturally appropriate manner.

## Future Directions

Many of the current career assessment models point to the importance of understanding personal variables that influence career development. Multicultural career assessment models look beyond person variables and take into account the context and environmental variables that affect career decisions and career development. Current multicultural models also suggest that one theory or technique may not be suitable or culturally valid to all clients. In other words, a general approach to assessment with all clients disregards relevant factors affecting the career issues of culturally diverse clients. Important environmental and contextual factors include an individual's family influence, cultural background, racial/ethnic identity, acculturation, socioeconomic status, gender role expectations, worldview, environmental factors including societal barriers, and perceived personal strengths. These factors aid in the career assessment process by helping the client identify factors that may contribute to or influence his or her thoughts, feelings, or actions in the career development process. It is important for career counselors to be aware of their own perceptions and beliefs about environmental factors that influence their own lives to prevent these from biasing their understanding of the concerns experienced by their culturally diverse clients.

Investigating the validity of current measures in use for research and practice has been one of the major thrusts in the recent past. The issue of whether career assessments need to be culturally valid or culturally specific remains a question for future multicultural career assessment research and practice. To continue to advance the area of multicultural career assessment, research is needed to examine whether these multicultural career assessment models are effective with culturally diverse clients.

---

## MULTICULTURAL CAREER COUNSELING CHECKLIST

---

As societies, especially in the United States, have become more diverse, counselors are expected to be

able to deliver competent services to a wide variety of clients. Such competency concerns call for measures that facilitate professionals collecting and managing the data needed for meaningful and successful interventions in cross-cultural career counseling. The Multicultural Career Counseling Checklist (MCCC) is a 48-item precounseling instrument designed for counselors to use as they prepare to see a client who is seeking career counseling and is especially valuable if the client is of a different race or ethnicity from the counselor. The MCCC was designed by Connie Ward and Rosie Phillips Bingham to assist counselors during initial interventions with ethnic and racial minority clients. The instrument is arranged in three sections: Counselor Preparation, Exploration and Assessment, and Negotiations and Working Consensus.

First, the counselor completes the sections under the heading of Counselor Preparation. The questions are designed to help the counselor focus on issues of the counselor's worldview, racial identity development, socioeconomic status, and political views. The section also asks counselors to review their general knowledge of and stereotypes about the client's ethnic or racial group.

Under Exploration and Assessment the counselor is challenged to conceptualize the client's presenting career questions. This section prods the counselor to sort through the cultural and familial issues that might be interacting with basic career concerns. The counselor must further explore the extent to which the client has already been exposed to career exploration material and role models. These aforementioned steps enable the counselor to determine the appropriate intervention and whether or not the intervention should focus on traditional career intervention methods, familial concerns, self-efficacy questions, or issues of societal structural barriers such as sexism and racism.

The third section on Negotiations and Working Consensus enables the counselor to reflect on the extent to which the client has been involved in framing the presenting career issue. One statement directly addresses whether or not the client and counselor have agreed on that career question. Furthermore, the counselor is challenged to make sure that he or she understands the client's career aspirations, expectations, and level of confidence. The section ends with statements regarding the type of career assessment instrument the counselor will use while working with the client.

The MCCC is a simple and straightforward self-analysis instrument that requires no specialized training beyond that acquired in most appropriate graduate programs. Practitioners, educators, and students can use this instrument to assess their deficits or questions around multicultural career counseling as well as provide a map to better understanding career issues for diverse clientele.

## MY VOCATIONAL SITUATION SCALE

---

The My Vocational Situation (MVS) scale is a self-report screening tool developed for use with high school, college, and adult career counseling clients. The MVS was authored by John L. Holland, Denise Daiger, and Paul G. Power. After a 10-minute administration time, it provides information on clients' vocational identity status, knowledge of career information, and applicable career barriers.

The majority of the inventory is comprised of the Vocational Identity subscale, which is made up of 18 true and false items. Vocational identity is one of the secondary constructs within Holland's popular theory of careers and defined as stable and clear goals, interests, and abilities. The MVS also includes an Occupation Information subscale, which assesses for

lack of vocational training or knowledge of career information through 4 yes or no items. The third subscale, Barriers, is a 4-item yes or no scale that assesses for environmental and personal barriers related to career decision making.

The results from the three scales can be used to determine if a client's difficulty in the career development process stems from low vocational identity, a lack of appropriate information, multiple barriers to his or her goals, or a combination of these issues. The results can inform the interventions that a career counselor may use with a client. Scores are based on the sum of all *false* and *no* answers. Therefore, higher scores on this measure are positive, indicating more stable vocational identity.

The norm group for the MVS comprises just over 1,000 individuals, including high school students, college students, full-time workers, and a few graduate students and university faculty. The test authors admit that the normative data were gathered haphazardly. The Vocational Identity Scale has the most acceptable psychometric properties, with some rather questionable reliability data reported for the other two scales. Some validity evidence is available for the MVS. This evidence is most inconsistent for the Occupational Information and Barriers subscales. Therefore, the reliability and validity evidence does not support the use of the Occupational Information and Barriers subscales to make decisions about individuals' career development status.

The MVS is published and available for purchase through Consulting Psychologist Press in its paper and pencil form. It is available for purchase in computerized format from Psychological Assessment Resources when bundled with the Self-Directed Search.

## NARRATIVE CAREER COUNSELING

---

Narrative career counseling represents a shift from the 20th-century focus on objective interventions for career decision making toward a 21st-century concern for interpretive approaches. It is sited in postmodern developments where previous grand theories overemphasize either social structures (e.g., Marxism) or individual psychology (e.g., psychoanalysis). Narrative career counseling moves away from a scientific approach that is exemplified by the matching of relatively static personality traits with job factors. Narrative approaches recognize that as dynamic social actors individuals speak, act, and interpret events through their particular contexts and cultures. In other words, it views career decision making as a holistic process, recognizing that the career story is shaped by the increasing complexities of life in a diverse social world.

To assist individuals make career decisions, many narrative practitioners use techniques that seek to reveal life-career themes. By focusing on aspects such as key events, early memories, favorite characters from stories, and role models, the stories that are re-collected give an indication of the dominant themes that are the preoccupations for the individual. This process situates the self as the main character in the story, where individual meaning rather than historical fact is placed in the foreground. The aim is to develop the story by recognizing the themes, exploring the related career interests, and helping the individual to draft future possibilities. Narrative approaches recognize

that as part of the sequence of moving from the past and present to the future, a period of indecision is necessary where potential career ideas can be tested. It is the action taken in the testing and enactment stages that moves the story on; without this action, the approach could be stuck in reflective storytelling. This approach provides a reality-testing element where the potential new story is evaluated in regard to its fit with the rest of the individual's life and includes recognizing the part that significant others play in career decision making.

The approach is empowering since the individual takes an active part in defining career roles that fit into his or her own understanding of meaningful life events. It provides a telling way of assessing an individual's career counseling needs, revealing more than objective assessment methods. Many practitioners will incorporate objective methods at a later stage, once the individual has developed a self-concept. Inevitably what the person recounts when telling his or her story is subjective, but life is subjective and people understand their own experience and that of others through the medium of storytelling. Such subjective exploration leads to the identification of goals and actions that are more meaningful for the individual and consequently more likely to be successful.

## NATIONAL CAREER DEVELOPMENT ASSOCIATION

---

The National Career Development Association (NCDA) is the oldest nonprofit counseling professional organization in the United States. Its mission is “to promote the career development of all people over the life span.” It currently has about 4,000 members that include career counselors, consultants, counselor educators, students, and career service providers such as career development facilitators (CDF), career coaches, and human resource personnel. The following describes the history and governance, professional services, and future directions of the organization.

### History and Governance

NCDA was established in 1913 as the National Vocational Guidance Association and changed to its current name in 1985. It is one of the founding divisions of the American Counseling Association (ACA). There are four individual membership categories: regular (joining NCDA directly), professional (joining through ACA), student or new professional, and retiree. In addition, three special membership categories recognize individual members who (a) have made significant contributions to the field of career development (Fellows), specialize in career counseling (Master Career Counselors), or specialize in career development services (Master Career Development Professionals). Professional organizations in other countries with missions similar to NCDA’s can join as international affiliates.

NCDA’s members have the authority to elect officers and vote for major decisions such as bylaws changes. The executive body is the board of directors comprising elected officers including the president, president-elect, past-president, secretary, treasurer, ACA governing council representative, two trustees-at-large, and four regional trustees. Day-to-day

operations are handled by the NCDA headquarters, which include an executive director and several staff members. There are more than 30 committees or task forces that implement special projects of the organization. Finally, there are 28 state career development associations that have a similar mission as NCDA, and their bylaws are approved by NCDA.

### Professional Services

NCDA provides a variety of professional services to its members, nonmember professionals and students, the general public, and international entities. These services include (a) professional community and networking (conferences, newsletter, Web site, electronic forums, mentoring program, international collaborations); (b) professional ethics, standards, and guidelines (for practice, education, and accreditation); (c) recognitions (awards, special membership categories); (d) publications and media (journal, books, Web-based magazine, DVDs, videotapes, audiotapes); (e) professional development and training (conferences, professional development institutes, continuing education programs, CDF training); (f) research (grants and awards, research projects); and (g) public relations and advocacy (marketing, press and media, consumer guidelines, national career development month, diversity, government relations, public policy making). These services are funded by membership fees, product or service revenues, grants, donations, or contracts. Three signature products of NCDA are its official journal (*The Career Development Quarterly*), Web-based magazine (*Career Convergence*), and CDF training curriculum.

### Future Directions

Currently NCDA is heading toward the following directions: (a) multiculturalism and internationalization, (b) collaborations with other organizations, (c) social advocacy and public policy making, (d) online curriculum (e-learning) for CDF training, and (e) revising and creating professional guidelines.

## NATIONAL SURVEY OF STUDENT ENGAGEMENT

---

The National Survey of Student Engagement (NSSE) obtains, on an annual basis, information from tens of thousands of students at hundreds of colleges and universities nationwide. The NSSE survey, administered during the spring academic term to randomly selected first-year students and seniors, asks about their participation in programs and activities that institutions offer for learning and personal development. The results provide an estimate of how undergraduates spend their time and what they gain from attending college.

The voluminous research on college student development shows that the time and energy students devote to educationally purposeful activities is the single best predictor of their learning and personal development. Those institutions that more fully engage their students in the variety of activities that contribute to valued outcomes of college can claim to be of higher quality compared with other colleges and universities where students are less engaged.

Survey items on NSSE represent empirically confirmed “good practices” in undergraduate education—behaviors by students and institutions that are associated with desired outcomes of college. Toward this end, NSSE asks students to report the frequency with which they participated in dozens of activities that represent good educational practices, such as interaction with faculty members and advisors, special programs, and other opportunities for learning and development that the college provides. Additional items assess the amount of reading and writing students did during the current school year; the number of hours per week they devoted to schoolwork, extracurricular activities, employment, and family matters; the nature of their examinations and coursework; and whether

they took part in a learning community, an internship, community service, study abroad, or research with a faculty member.

In addition, students report their perceptions of the college environment, such as the extent to which the institution offers the support they need to succeed academically and the quality of relationships among various groups, such as faculty and students. Students also estimate their educational and personal growth since starting college in the areas of general knowledge; intellectual skills; written and oral communication skills; personal, social, and ethical development; and vocational preparation. Students also provide information about their background, including age, gender, race or ethnicity, living situation, educational status, and major field.

Institutions receive a series of comparisons that allow them to review their performance alongside that of peer institutions, their Carnegie type, and national norms. Also, schools get a data file with their students’ responses so that they can conduct additional analyses if they have local institutional review board approval to do so.

Institutions use NSSE data to identify aspects of the undergraduate experience inside and outside the classroom that can be improved through changes in policies and programs. This information can also be used by prospective college students, their parents, college counselors, academic advisers, institutional research officers, and researchers who wish to learn more about how students spend their time at different colleges and universities and what they gain from their experiences.

---

## OCCUPATIONAL HEALTH PSYCHOLOGY

---

The goal of occupational health psychology (OHP) is to improve the quality of work life, and to protect and promote the health of workers and of their families. OHP is interdisciplinary, involving most areas of psychology and drawing upon fields such as public health, sociology, medicine, and industrial engineering. OHP is typically characterized as having a three-fold focus on the work environment, the individual worker, and the interface between work and family. Interventions and/or research range across all three levels (primary, secondary, and tertiary) of the public health model of prevention.

### Historical Roots

In many respects, OHP grew out of efforts to understand, and later to remediate, the impact of the widespread application of Frederick Taylor's management principles on workers in both the United States and Europe. Nearly a century ago, Taylor argued that industrial productivity can be improved by simplifying, compartmentalizing, and standardizing worker tasks. Thinking about work was considered the domain of managers, while doing the work (without thinking) was the role of the mass of workers. At its most extreme, the Taylor approach aims to make workers interchangeable and the emotional responses or perceptions of workers are considered irrelevant.

Although the Taylor approach has always had detractors, particularly among organized labor, it wasn't until the 1960s that researchers began to investigate

the links between one's work life and one's physical and emotional health. Much of this seminal research was conducted in Europe, particularly in Scandinavian countries. Prominent among these efforts were Robert Karasek's studies demonstrating that workers who experience high job demands and have low decision-making latitude tend to experience poorer mental health and are at increased risk for cardiovascular disease. Researchers began focusing on ways to redesign jobs to improve worker health and satisfaction. Others investigated the impact of un- and/or underemployment on workers. Contrary to the precepts of the Taylor management approach, it is now recognized that many of the same factors associated with physical and mental health (stimulation, variety, task control, autonomy, etc.) are also associated with higher levels of job performance.

In the United States, the National Institute for Occupational Safety and Health (NIOSH) has been a leader in researching work-related stress. Although occupational safety and health often seems to concern itself only with traumatic injuries and toxic exposures, it is significant that the Occupational Safety and Health Act of 1970 that created NIOSH specifically recognized the need to investigate the role of psychological factors related to occupational safety and health. In 1990, NIOSH partnered with the American Psychological Association (APA) to fund the initial development of OHP curriculum at 12 universities in the United States. This partnership also led to a series of conferences on topics related to work organization and work-related stress. Recently, the newly formed Society for Occupational Health Psychology joined NIOSH and APA as a conference sponsor and plans

have been formalized for future conferences to be held biennially. In 1996, the partnership between NIOSH and APA also gave birth to the *Journal of Occupational Health Psychology*.

### Areas of Emphasis

As was discussed earlier, OHP can trace its roots to investigations of the impact of Taylor management principles on the emotional and physical health of workers. However, this early focus has broadened considerably in the last 25 years. During this time, there have been significant changes in the structure of work in both the United States and Europe. Many manufacturing jobs were lost and economies shifted toward service jobs. In the last 2 decades, corporate mergers and downsizing efforts left many workers needing to switch employment, if not careers, often accepting lower incomes, in their 40s and 50s—ages that previously were associated with stable employment and peak earning potential. Companies have moved away from making long-term commitments to employees, relying instead upon temporary workers and/or contractors. Correspondingly, there has been an increase in the number of self-employed people. All of these changes were accompanied by stress, both for workers losing or changing jobs and for those retaining employment, but needing to adapt to new contingencies.

### Work Organization

In addition to the structural changes discussed above, to remain competitive, many employers significantly changed management systems, supervisory practices, and production processes. Among these changes are compressed work schedules, flexible work schedules, home-based work, lean management, and an increased reliance on technology. These practices are intended to increase the ability of companies to respond quickly and efficiently to changing production demands without compromising quality. However, employees are working longer and harder and often bear greater responsibility for outcomes, though not always with increased decision-making latitude. Learning new processes and new technologies places increased cognitive demands on workers, leading to stress that has been tied to negative health effects.

### Gender

Women continue to make inroads into previously nontraditional occupations ranging from construction sites to corporate boardrooms. In addition to the stress of entering occupations whose cultures and practices have been shaped almost exclusively by men, working women must weigh the impact and timing of having children on career. Despite major changes in perceptions regarding gender roles, women continue to bear major responsibility for child rearing and household functioning, thereby increasing stress related to balancing the conflicting needs of work and family.

### Aging Workers

The workforce is aging. In part, this shift simply reflects the demographics of the baby boom and in part people working longer, either by choice or by necessity. In Europe, this shift has been driven by declining birthrates. There are simply not enough replacement workers being born. Consequently, there is great interest in keeping older workers healthy and satisfied enough to remain working. In some European countries this has been a major factor in the development of OHP. Although older workers are more reliable, bringing the wisdom and skills of decades to jobs, they also tend to be less physically robust than younger workers. They are more sensitive to changes in the work environments such as extremes of temperature and poor lighting. In instances where an older person is working in a low-level service job (to supplement retirement income), supervisors are often years younger. This can lead to stress when the older worker is subjected to stereotypes about the elderly or is held in low regard because of the unskilled nature of the work.

### Race and Ethnic Diversity

It is estimated that by the year 2050, 15% of the American workforce will be Hispanic. Areas of the United States, such as the Southeast and the Midwest, that have not traditionally been destinations for Hispanic immigrant workers have experienced explosive growth in the size of their Hispanic communities. In addition to political issues and legal consequences related to some immigrants' undocumented status, Hispanic immigrants in these "new settlement areas"

are further socially marginalized and subject to exploitation due to lack of a Spanish-speaking public and/or social services infrastructure. These immigrants tend to be employed in the least desirable, poorest paid, and most dangerous occupations, so they are at increased risk to suffer from negative health consequences. However, even when working side by side with Americans, Hispanics immigrants suffer from significant occupational health disparities. For example, Hispanic immigrants working in construction are killed at 2–3 times the rate of American-born workers performing the same jobs. Contrary to popular perceptions, less than 1% of Hispanic immigrants work as day laborers. The remainder work for companies ranging in size from small businesses to international corporations.

Within the European Union, most legal barriers to the flow of workers from one country to another have been eliminated. Consequently, more prosperous economies have seen an influx of nonnative workers. For example, Ireland, with a population of less than 5 million, has the same proportion of nonnative workers as does the United States. Whereas the United States is challenged to simply meet the needs of Spanish speakers, Ireland must attempt to overcome barriers of language and culture for a half dozen nationalities.

### Influencing Change

Although the rapidly changing world of work seems a moving target, there are many opportunities for OHP to influence change for both the employer and the individual. On the employer level, the spiraling of health insurance costs offers a strong economic argument for employers to redesign jobs and to develop interventions aimed at reducing work-related stress (and its associated illnesses). Employers also need help adjusting to an increasingly diverse workforce. On the individual level, workers are expected to take increasing responsibility for their career trajectories. Making a good initial choice of career represents solid primary prevention of work-related stress. However, many workers need assistance with adjusting to ongoing change in their jobs. Workers and employers need assistance in preventing new communication technologies from blurring the boundaries between work and home to the detriment of family life.

## OCCUPATIONAL INFORMATION

---

Occupational information is one of the major components needed to make effective career decisions. Occupational information refers to the collection of details about occupational and educational opportunities. Gathering and using occupational information is essential if an individual is to select options that fit his or her interests, values, aptitudes, and skills. Occupational information can include details about the employment outlook, salary, related occupations, education and training, and job duties.

Occupational information can be classified using three types of classification systems. Classification allows individuals to communicate more effectively with students about occupations that share common characteristics. The most widely used occupational classification systems include the Standard Occupational Classification (SOC) System, Holland's Hexagon, and the World-of-Work Map (WWM). The SOC system classifies occupations based on the nature of the work performed and on the occupational skills, education, and training requirements for the job. Holland's hexagon classifies occupations in terms of six personality dimensions based on Holland's theory of personality and work environments: Realistic (R),

Investigative (I), Artistic (A), Social (S), Enterprising (E), and Conventional (C). A basic premise of Holland's theory is that individuals will find more satisfaction when their work personalities are congruent with the characteristics of their work environment. The WWM was developed by ACT, Inc., and can be used to suggest occupations to users who enter the map with a set of attribute scores. The position of occupations on the WWM is based on the degree to which an occupation requires working with data, ideas, people, and things. Similar to Holland's hexagon, individuals can also be located on the WWM based on the degree to which they express an interest in working with data, ideas, people, and things.

Another important component of occupational information is the source from which the information can be obtained. Major sources of occupational information include print materials and computerized information systems.

Printed sources of occupational information include Occupational Information Network (O\*NET) and the *Occupational Outlook Handbook (OOH)*. O\*NET is a comprehensive system for organizing, describing, distributing, and collecting data on occupations and the workforce. The *OOH* includes information about the nature of work, working conditions, the distribution of work, training required for occupational entry and advancement, average earnings, and projected 5- to 7-year employment outlooks.

Computerized sources of occupational information such as SIGI PLUS and DISCOVER are computer-assisted systems used to learn about oneself and the world of work. SIGI PLUS includes modules on self-assessment, search strategies, information, skills, preparing, coping, deciding, and career planning. Similar to SIGI PLUS, DISCOVER includes self-assessment inventories, searchable academic and occupational databases, and information to help students explore themselves and the work of work.

In order to make quality educational and career choices, students should engage in gathering accurate occupational information. Through the use of occupational classification systems and various sources of occupational information, students will find it easier to form realistic pictures of the career opportunities that are available in various occupations.

---

## OCCUPATIONAL INFORMATION NETWORK

---

The Occupational Information Network (O\*NET) is the United States Department of Labor's online successor to the *Dictionary of Occupation Titles (DOT)*. The O\*NET is intended to provide a reference responsive to the rapidly changing world of work. The O\*NET is an ever-evolving resource due to ongoing data collection efforts intended to expand its information coverage and regular updates to ensure an accurate reflection of the current economy and labor market. Consequently, information available online may differ according to date of access.

Unlike the *DOT*, which focused on very careful descriptions of specific job titles, the O\*NET organizes information to facilitate identification of commonalities across jobs. The Crosswalk system allows users to reference occupational information across several classification systems. Within the O\*NET, occupations are organized using the Standard Occupational Classification (SOC) system, which clusters similar jobs. Consequently, for a given job

some descriptions may be less precise than in the *DOT*, as the descriptions reflect an entire SOC cluster, not just that specific job.

The O\*NET classifies occupations along the major dimensions of vocational interests, work values, and ability requirements. Drawing upon major person–environment fit models, the O\*NET characterizes vocational interests using Holland’s theory of vocational personalities and work environments and work values using the theory of work adjustment. This organization was directly influenced by the counseling model used by the Vocational Assessment Clinic at the University of Minnesota, a model intended to operationalize the most important elements of the theory of work adjustment.

### O\*NET Database

The O\*NET database is intended to be a comprehensive source of descriptors for the occupations (approximately 950) considered most important to the United States economy. These descriptors include ratings of importance, level, frequency, or extent for the following variables: skills, abilities, knowledge, tasks, work activities, work context, experience levels required, job interests, and work values–needs. The methods used to generate these descriptors include expert judgments, field observations, and worker self-report. Although the database is of great interest to researchers, average information seekers would find it very difficult to access.

### O\*NET OnLine

The O\*NET OnLine is a Web-based viewer intended to provide access to O\*NET information for a broad range of users (from students and job seekers to human resource professionals). Its uses include finding and exploring occupations, searching for occupations that use designated skills, viewing occupation summaries and details, cross-referencing other occupational classification systems, identifying related occupations, and linking with other online resources, such as current wage and employment outlook information.

### O\*NET Career Exploration Tools

The O\*NET Career Exploration Tools are a set of assessment tools intended to facilitate career exploration

by helping individuals to identify their vocational interests, work values, and abilities. The Career Exploration Tools include the *O\*NET Interest Profiler*, the *O\*NET Work Importance Locator*, the *Work Importance Profiler*, and the *O\*NET Ability Profiler*.

## OSIPOW, SAMUEL H. (1934– )

---

Samuel H. Osipow is one the pioneers of vocational psychology in the United States. Graduating with a Ph.D. from Syracuse University in 1959, Osipow worked for 6 years as a counseling psychologist at Pennsylvania State University before taking a faculty position in the Psychology Department at Ohio State University. He spent the bulk of his academic career at Ohio State University from 1967 to 1998, 13 years of which he served as its chair. Within his academic career, Osipow published over 200 journal articles and book chapters and 18 books and monographs. He was a Fellow of the American Psychological Association

(Divisions 13, 15, 17, & 35), the Association for Psychological Science, and American Association for the Advancement of Applied and Preventive Psychology. His 13 years as Chair of the Psychology Department at Ohio State University as well as his numerous accomplishments within the American Psychological Association are also a testament to his unusual leadership abilities as well as his true integration of the scientist and practitioner aspects of his own career.

He wrote one of the first textbooks in the field of vocational psychology, *Theories of Career Development*, which was first published in 1968 and revised three times, most recently with Louise Fitzgerald in 1996. His numerous professional accomplishments and achievements include serving as the founding editor of the *Journal of Vocational Behavior*, editor of the *Journal of Counseling Psychology*, and editor of *Applied and Preventive Psychology*. With W. B. Walsh, he also coedited the first and second edition of the *Handbook of Vocational Psychology*.

Osipow also made significant contributions to career assessment. With some students, he developed the Career Decision Scale, one of the first career decision-making measures for the field. This work was then expanded in his collaboration with his colleague, Itamar Gati from Israel, in the development of the Career Decision-Making Difficulties Questionnaire. With the assistance of Arnold Spokane, he also developed the Occupational Stress Inventory, a comprehensive measure of occupational stressors, strains and coping resources published by Psychological Assessment Resources.

Osipow was also very active within the Counseling Division and within the American Psychological Association's (APA) governance. He served for many years on the Executive Board of the Division of Counseling Psychology (Division 17), culminating in

his election to the Division's Presidency in 1977. The Counseling Division also bestowed upon Osipow its highest honor by awarding him the Leona Tyler Award in 1989. Within APA, Osipow was elected to the APA Council of Representatives for two terms, served as Chair of the Education and Training Committee, Chair of the Council of Editors, Chair of the Publications and Communications Board, and on the Board of Directors. He was also Chair of the National Register of Health Service Providers in Psychology Board of Directors. In recognition of his significant and lifelong contributions to career counselors, the National Career Development Association awarded Osipow its Eminent Career Award in 2000.

## PARSONS, FRANK (1854–1908)

---

School leavers in the late 19th century in the United States faced a multitude of unfamiliar job opportunities in the developing industrial economy of the Gilded Age. Although a few schools attempted to provide occupational guidance, only one individual, Frank Parsons, established the first vocational guidance clinic and articulated the basic principles of vocational guidance from which the profession of vocational counseling developed.

Parsons, born in 1854, attended Cornell University and studied to become a civil engineer, a vocational goal in that era as prestigious as becoming a computer engineer is today. He succeeded in finding employment with a railroad industry, again the equivalent today of going to work for a major software company. But in the economic depression of 1873, his employer was forced into bankruptcy and Parsons found himself out of a job. After a period of working as a manual laborer, he was able to find several successive positions teaching art and literature in the public schools. Ultimately he “read” for the law and became a member of the Massachusetts Bar.

In the 1890s, Parsons was very active in Populist and Progressive causes while teaching classes at Boston’s YMCA as well as at Boston University Law School and Kansas State University. He was recruited to teach the class *The World’s Best Books* at Civic Service House, one of the new settlement houses that offered support to Boston’s Italian, Jewish, and other immigrants. He became director of their program called the Breadwinner’s Institute, a kind of evening

high school, and he soon conceived the Vocation Bureau to help Boston’s citizens find careers for which they were best fitted.

Opening in 1908 with three staff members, one a woman, and an advisory board drawn from Boston’s civic leadership, Parsons reported that in its first 4 months the bureau served 80 young men and women ages 15 to 39 years. And, “according to their own spontaneous statements, all but two . . . received much light and help, some even declaring that the interview with the Counsellor [sic] was the most important hour of their lives” (Parsons, 1909, p. 30).

Parsons died before the first year of the bureau was completed, but in a book compiled from his papers, he stated the principles of vocational choice as follows: (1) a clear understanding of yourself and your aptitudes, interests, ambitions, resources, and limitations and their causes; (2) a knowledge of the requirements and conditions of success, advantages and disadvantages, compensation, opportunities, and prospects of different lines of work; and (3) true reasoning on the relation of these two groups of facts. The first two of these principles are highly developed contemporary components of vocational counseling (or career development) practice. Standardized ability tests were being developed in Parsons’s time, and interest inventories followed in the next decade. Today, the Web and every library offer a multitude of occupational information sources. Parsons did not elaborate on his concept of true reasoning. Probably it is equivalent with decision making and career planning as we now know it and is much of what the process of career counseling and development is about.

Parsons should be celebrated as the founding father of vocational psychology. The principles he articulated in support of it continue to be valid a century later.

## PART-TIME WORK

---

Part-time refers to work performed by laborers who work less than the standard number of hours and who are often ineligible to participate in an organization's benefit plans. Many organizations need part-time workers to be successful. Organizations use part-time workers for several reasons: to meet the demands of the labor-intensive economy and cyclical economic patterns, to provide flexible scheduling, and to lower labor costs. According to the U.S. Department of Labor's Bureau of Labor Statistics there were over 24 million part-time workers in the United States in both 2004 and 2005, consisting of approximately 16% of the civilian labor force. The increasing number of part-time workers is also apparent in other parts of the world such as Europe and New Zealand. Because of their importance, organizations must retain part-time workers, a need that opens the door for acknowledging the importance of career counseling for, working with, and helping part-time workers, specifically in terms of their retention in organizations.

### Uniqueness of Part-Time Workers

#### *Characteristics of Part-Time Workers*

The classification of worker as full-time or part-time is determined by the standard used by the reporting government. In general, part-timers work less than 40 hours per week. Most part-time workers are paid

by the hour (the median weekly earnings for part-time workers in 2005 was \$201) and are not part of their organization's benefit plans that include vacation, pension, insurance, and other benefits. Two thirds of part-time workers are female. One third of part-time workers are in sales and office occupations (e.g., sales and administrative support); another 25% are in management, professional, and other related occupations; and another 25% are in service occupations.

Not only do part-time workers differ from full-time workers, but they also differ among types of part-time workers. Part-time workers may be permanent or temporary, organization- or agency-hired, year-round or seasonal, voluntary or involuntary, or they may moonlight. Additionally, part-time positions may be classified according to cyclical businesses (e.g., construction), secondary work (e.g., fast-food services), or retention-oriented jobs.

Many part-time workers are highly skilled, career-committed, and want career development, but a variety of reasons necessitate these people work part-time. According to the Bureau of Labor Statistics, approximately 12.5% of all part-time workers believe that economic reasons drive their need to work part-time, which includes business conditions, seasonal work, and the unavailability of full-time work. The majority of people who work part-time give noneconomic reasons for their position, such as child care problems, retirement, other family or personal obligations, or school or training obligations.

### *Part-Time Workers*

Part-time workers obviously work less than the standard number of hours that full-timers work. However, the differences between part-time and full-time workers cover much more than just this simple classification distinction. People with certain job attitudes and behaviors may be drawn toward part-time work. The goals, attitudes, motivations, and outcomes associated with part-time workers can be very different from those associated with full-time workers. This difference can be crucial in terms of career counseling and working with part-timers, especially when the topic is their retention in organizations. In other words, practices and methods used for the retention of full-time workers may be quite different from those used for part-time workers. A definite difference exists between part-time and full-time workers. Career counselors and others who work with part-time

workers such as managers and supervisors or those working in the human resources and training fields must understand that part-time workers cannot be treated the same as full-time workers. Part-time workers have a definite psychology of work that is different from that of full-time workers. Those who work with part-time workers must understand these differences and apply this information in order to effectively counsel and work with a part-time worker population, especially when considering their retention in the workplace.

Retention rates of part-time workers are far less than those of full-time workers. Thoughts of quitting, job satisfaction, expectation of finding alternatives, and intention to quit were highly related to retention rates of full-time workers; however, none of these variables were related to retention of part-timers. In effect, part-time workers do not make decisions regarding their retention in organizations the same way as full-time workers; part-time workers have a different psychology of work. Therefore, management policies and practices geared specifically for part-time workers need to be considered.

### **Social Exchange Theory**

Several researchers believe part-time workers feel less included, less connected, and less involved in their organization, or they do not feel they are tied to or part of the organization like their full-time counterparts. Social exchange theory may give insight into retaining part-time workers. In short, social exchange theory explains that relationships are built upon a fair exchange of goods or currency. Relationships start when one person gives or does something for another person and continue when the other person reciprocates. This theory may also be used as the basis for working with part-time workers. If organizations can make part-time workers feel as if they are part of the organization through pay; through support of and care for their well-being; through valuing their work, thoughts, and opinions; and through relationship building, those same part-time workers may feel obligated to repay the organization by staying with the organization.

### **Researcher Recommendations**

As one can see, part-time workers are a different entity than full-time workers. Some have said that temporary, involuntary, agency-hired, and seasonal

part-time workers who are working two jobs will be less involved and committed to their work and organization than those part-time workers who are working only one job that is permanent, year-round, and organization-hired. Moreover, differences among part-time workers themselves bring the need to treat and work with part-time workers appropriately. For instance, older workers may prefer work arrangements that are organization-hired, while females may want work arrangements that are agency-hired.

Over the years, researchers have given several recommendations for dealing with part-time workers. For instance, part-time workers may not be worried so much about salary as they would be with scheduling flexibility and recognition for their work. Part-timers want work that is satisfying, challenging, and interesting and that enhances their development as employees in the organization and people. Part-time workers want autonomy and a sense that they control things. Part-time workers want to feel they contribute to the organization and that their thoughts and opinions are heard and taken into consideration in decisions. Part-time workers also enjoy social interaction with their fellow workers, including interaction with their supervisors.

From a social exchange theory perspective, to increase retention of part-time workers, organizations must care for the development and well-being of their part-time workers. Part-time workers will then feel obligated to reciprocate and pay back the organizations by staying with the organization. Compensation and benefits are obvious ways to increase retention of part-time workers. However, as previously discussed, feeling part of the organization is very important to part-time workers. Organizations must provide programs to help part-time workers feel valued and wanted by the organization. Organizations must support the career development of their part-time workers. Organizations must strive to treat their workers fairly and must consider their interests when making decisions. Organizations must also consider work-life balance policies because many part-time workers are students or have family issues.

Management is also important in the retention of part-time workers. Management must attempt to give their part-time workers a voice at work in solving problems and in decisions that affect work. Management must communicate with their part-time workers about changes and other pertinent information. Management must also believe in giving part-time

workers responsibility and autonomy and must readily give recognition and praise for their work.

Organizations, management, and those working in training and human resources need to acknowledge that part-time workers are important to organizational success. Policies and practices geared toward their retention must attempt to make them feel tied to the organization or make them feel wanted. Career counselors must also be cognizant of this information. Part-timers have a variety of reasons for working the hours they do, from economic necessity, to family issues, to preference. Career counselors must understand the motivation of the part-timers they are helping. Career counselors must stress different ways to help part-timers feel connected to their organization to increase their retention. Career counselors can also work directly with organizations in implementing practices and policies that will increase the retention of part-time employees. By finding the right fit in terms of scheduling flexibility, autonomy, and support, career counselors can be helpful in making part-timers feel tied to their organization to increase their retention in organizations.

## PAY EQUITY

---

Pay equity is based on the principle that the payment an employee receives from the employer should be

proportional to his or her contributions to the organization. Otherwise, inequity results. Historically, pay equity has been approached by two somewhat separate perspectives: (1) the individual or psychological perspective, which focuses on how individuals form pay equity perceptions and the consequences associated with feeling inequity; and (2) the social or economic movement perspective, which concentrates on documenting objectively existing pay inequity at the societal level and on advocating its eventual elimination.

### **The Individual-Psychological Perspective**

According to J. S. Adam's equity theory, when forming pay equity perceptions, an individual evaluates the payment (broadly defined, including salary, benefits, promotion, social status, etc.) that he or she receives relative to the inputs (e.g., education, skills, experience, and effort) that he or she brings to a job and then compares his or her ratio of payment to inputs with other employees in a similar job. Two types of pay inequity result from the above social comparison: (1) overpayment, when the individual perceives that his or her ratio is larger than others; and (2) underpayment, when the individual perceives that his or her ratio is smaller than others.

Perceptions of overpayment lead to guilt. However, research suggests that this guilty feeling does not last long, and overpaid individuals quickly become accustomed to it, implying a fundamental self-serving bias. On the other hand, perceptions of underpayment lead to resentment, anger, and personal distress. These negative affects prompt underpaid individuals to restore equity. Due to the subjective nature of equity theory, it is difficult to predict specific strategies that underpaid individuals will adopt. However, a bulk of research shows that many of the strategies actually taken are detrimental to the organization: for instance, decreased motivation and productivity and product quality, lowered organizational commitment and pay-job satisfaction, increased counterproductive behaviors (theft, sabotage, and absenteeism), elevated intention to quit, and actual voluntary turnover.

Research suggests that some individual difference variables (e.g., positive affectivity and negative affectivity) as well as situational variables (e.g., participation in pay decisions) influence the formation of pay equity perceptions. There is also some evidence that individuals have varying degrees of equity

sensitivity that moderates the severity of their reactions to inequity perceptions. In addition, although individuals typically choose employees in a similar job as their comparison referent, D. M. Cowherd shows that many low-level employees also compare their rewards to those received by upper management.

### **The Social-Economic Movement Perspective**

Beyond the pay equity perceptions is the well-established fact that in the United States there has been a substantial wage gap across gender with men being paid more than women, aggregated on the national level. The past several decades saw one of the major social and economic movements attempting to eliminate such a gap. The ideological foundation of this movement is the principle of comparable worth, meaning jobs with similar worth to an organization should be paid equally, regardless of gender. Accompanying this movement were various legislative efforts to outlaw wage discrimination (e.g., Equal Pay Act of 1963, Civil Right Act of 1964, Title VII) and the establishment of the Equal Employment Opportunity Commission to enforce these acts. The size of the observed gender wage gap, or the ratio of women's wages to men's wages, has since shrunk slowly from 63% in 1979 to 77% in 2002.

Two schools of thought have tried to explain the persistence of the gender wage gap. The human capital explanation argues that the wage gap can be at least partially attributed to the differential amount of human capital men and women bring to the workplace. For instance, as compared to women, men tend to have more job qualifications in terms of education, skill, and experience and are more likely to have longer, more continuous careers. The discrimination explanation blames societal factors that place women in relatively disadvantageous positions in the workplace. For instance, gender segregation has been dominant throughout the American labor force, with women less likely than men to possess more prestigious, higher-paid jobs; to enter industries with strong trade unions; and to have few senior female managers in the organization hierarchy to serve as role models.

## PERFORMANCE MODELING

---

Performance modeling refers to the complex process of describing and defining job performance and facilitating the consequent goal of accurate prediction of job performance. It is a concept of particular significance in the area of industrial-organizational psychology as a measure of evaluation for the individual worker and the organization as a whole. Performance modeling also has a connection to the area of vocational psychology as well (i.e., the theory of work adjustment). It is this connection to vocational psychology that makes this concept additionally relevant to the practice of career and vocational counseling.

The idea of performance has generally been viewed from two perspectives: as the behavior of a person in the work setting and the extent to which this behavior produces a given output or result for the organization related to its goals. Job performance is a complex combination of several components and a concept to be distinguished from the related ideas of effectiveness (evaluation of performance results) and productivity (the cost-to-effectiveness ratio).

The classic model of job performance prediction fails to effectively predict performance due to weakness of predictor variables, confusing measures of these variables with the attribute being measured, and problems with the statistical analyses of this model. Campbell's model focuses on eight performance components across all jobs: job-specific task proficiency, nonjob-specific task proficiency, written and oral communication tasks, demonstrating effort, maintaining personal discipline, facilitating peer and team performance, supervision, and management-administration.

Borman and Motowidlo's model describes two components of performance: task performance and contextual performance. Task performance pertains to technical aspects of the job necessary to complete it, while contextual performance refers to activities contributing to the organizational environment and supporting its goals. Hesketh adds the dimension of adaptive performance to a model for job performance. According to Hesketh, this addition adds a cognitive component (related to a person acquiring new skills on the job) and a noncognitive component (related to coping skills and self-efficacy for change).

## PERSONAL AND CAREER COUNSELING

---

Personal counseling and career counseling share a significant history. Vocational or career counseling started with the work of Frank Parsons and his staff at the Vocation Bureau of Boston in 1908. Parsons would die shortly after the bureau began operations, but not before the term *counseling* emerged to describe the

services provided to clients of the Vocation Bureau. His book, *Choosing a Vocation*, would be published a year after his death, cementing the legacy of career counseling. Thirty years later Edmund G. Williamson would introduce the first counseling theory, which was based on the original work of Parsons.

Much of the description of counseling found in definitions ascribed to counseling by professionals and professional organizations can also apply to the definition of career counseling. Career counseling is a specialization of personal counseling much like other specialty areas of counseling (i.e., school, family, rehabilitation, etc.), which implies a particular emphasis, population, or setting for its practice. Counseling is a process that assists individuals in gaining helpful information about themselves, others, and the world around them as they problem solve or make decisions to improve their quality of life. Counseling emphasizes the value of individuals being able to make their own decisions. Counseling and its specialties, which include career counseling, provide their professional services for individuals, groups, or families. Counseling professionals may provide services through institutions such as schools, colleges, and universities, as well as in public agency and private practice settings. At the same time, personal counselors, including career counselors, may work in consultation with institutions or organizations.

As with any other counseling specialty, career counselors rely upon theory, research, and a set of specific skills (e.g., active listening) to assist their clients. Career counselors can assist clients with issues related to career information, decision making, and career or work adjustment related issues. Likewise, they can help clients deal with career-related changes and transitions such as pursuing a new occupation, retirement, or a career-related crises (e.g., downsizing). Career counselors use resources such as career information, technology, and assessment instruments to enhance their work with clients as clients acquire critical personal and occupational information during the career counseling process. Career counseling and other counseling specialties are typically viewed as briefer or shorter interventions than more clinically focused approaches (e.g., psychotherapy) found among professionals and professional settings where more pronounced clinical issues and diagnoses may be found (i.e., addiction settings, partial hospitalization programs, etc.).

The various kinds of personal counselors, including career counselors, have professional organizations

(e.g., American Counseling Association, American Psychological Association's Division 17: Society of Counseling Psychology, National Career Development Association) who advocate for professional standards, licensure, and certification. There are also accrediting bodies (e.g., Council for the Accreditation of Counseling and Related Education Programs, Council on Rehabilitation Education) to ensure that professional preparation standards are met by academic training programs. In accordance with professional organizations and accrediting bodies, minimum educational requirements (e.g., master's degree) and competency levels are suggested for various kinds of counselors, including career counselors, with a strong emphasis on ethical standards and practices.

## PERSONALITY ASSESSMENT AND CAREERS

The term *personality* typically refers to one's characteristic pattern of thinking, feeling, and behaving. In addition to the stable, trait-like features often evoked by this construct (e.g., sociability, dominance, modesty), many theories also emphasize the roles of culture, family, and other environmental factors involved in personality expression and development. This predominant individual differences variable has informed career assessment practices. Unlike many traditional personality assessments, which emphasized pathological functioning, contemporary career applications tend toward neutral to positive traits. Both quantitative and qualitative assessments based in personality theory are employed to assist clients with numerous career concerns. A growing body of research has shown important connections between personality constructs and a broad array of career behaviors including individuals' approach to learning, vocational interests, career choices, self-esteem, confidence in performing tasks, career counseling interactions, job searches, and subsequent work performance, satisfaction, and tenure.

### Foundations Connecting Personality and Careers

#### *The Big Five*

Building on decades of research within the lexical tradition, Paul Costa and Robert McCrae recently popularized the idea that there are five broad domains of personality traits, known as the Big Five: Neuroticism, Extraversion, Openness to Experience, Agreeableness, and Conscientiousness. This empirical approach describes relationships between personality descriptors that have been encoded into language systems. The NEO Personality Inventory-Revised is frequently used to assess the Big Five and 30 more specific facets (e.g., Fantasy, Impulsiveness, Order) relevant to career choice and performance. Many personality assessments comprise different aspects of the Big Five related to career counseling.

Individually, these broad domains affect how clients might interact with counselors or approach work tasks and settings. For example, extraverts, who tend to be more sociable and active, might prefer people-oriented occupations and are more likely to be

talkative and enthusiastic during counseling sessions. Those high on Openness frequently have wide interests, which may interfere with their ability to commit to one career option. Their openness to new ideas and imaginative qualities also increase receptivity to novel counseling interventions. Given their attention to details and dutiful approach to tasks, conscientious individuals often demonstrate greater job performance. Moreover, highly conscientious individuals likely show greater motivation to engage in the challenging tasks involved in planning a career. By combining two or more of the Big Five domains, even more refined insights are possible. For example, levels of Openness and Conscientiousness can inform one's approach to learning. Those high on both may flourish in an academic setting because they are naturally curious, have greater aspirations, and are motivated to seek high goals. However, those high on Openness, but low on Conscientiousness, might struggle to realize their imaginative ideas due to lesser diligence or achievement motivation.

#### *Holland's Typological Theory*

John Holland's prominent personality theory of vocational types has generated almost 50 years of research informing career assessment. Holland identified six broad types of individuals and postulated that people will achieve greater work satisfaction by selecting work environments that match their vocational personality type. These six types, briefly summarized below, represent syndromes that include qualities related to individuals' preferred activities, goals, work values, and perceived abilities:

**Realistic:** Mechanical or hands-on tasks including agriculture, nature, operating machines/tools, and manufacturing, often in outdoor settings.

**Investigative:** Analytic tasks involving math, science, or research.

**Artistic:** Creative, unstructured tasks including music, fine art, drama, or writing.

**Social:** Helping, supporting, or teaching others.

**Enterprising:** Leading or persuading others.

**Conventional:** Structured tasks involving organizing data in office or financial settings.

These six types have been operationally defined by Holland's Vocational Preference Inventory in 1958 and the Self-Directed Search in 1985. Most major interest inventories now incorporate measures of Holland's types (e.g., Kuder Career Search, Strong Interest Inventory). Holland's theory is a foundation for career counseling and taxonomies for organizing occupational information, including for the *Dictionary of Occupational Titles* and the Occupational Information Network (O\*NET). Counselors assist clients in identifying their top Holland scores and then in exploring occupational possibilities that match their work personality. Other important factors considered include abilities, work values, and needs. Astute counselors help clients integrate information across these important life domains to construct a meaningful career path through maximizing overlap between their personality and opportunities.

### ***Linking the Big Five With Holland's Big Six***

An accumulation of studies examining areas of convergence between the Big Five and Holland's Big Six yielded numerous connections. Extraversion relates to Holland's Social and Enterprising themes, Openness relates to Artistic and Investigative, and Agreeableness slightly relates to Social. Taken together, these two theories can enhance career counseling by noting their similarities and differences. The Big Six may be more useful for selecting occupations, whereas the Big Five inform how one approaches occupational tasks.

### **Assessing Personality to Inform Career Counseling**

Most personality measures used in career counseling are quantitative and present results comparing the test taker's scores with those from a normative sample. For example, a client may score at the 95th percentile on a measure of Extraversion compared to other adults. The counselor can compare this result with the vast literature on typical career choices and behaviors of extraverts. Other approaches emphasize the unique patterning of scores of specific individuals incorporating their sociocultural context. Combining quantitative scores from standardized measures with insights gained from qualitative approaches such as sentence completion or narrative techniques examining clients'

individual strivings and work values can elucidate unique career stories. Together, counselors and clients can explore how personality features affect career/life decisions and concerns. The following prominent personality assessments have been applied to career counseling.

The Myers-Briggs Type Indicator (MBTI) is the most widely used personality assessment applied to nonclinical populations. Based on Carl Jung's earlier ideas on personality, Katherine Briggs and Isabel Briggs Myers developed this measure in the 1940s to assign individuals to one of 16 MBTI types based on four dichotomies separating (1) one's source and direction of energy (Extraversion vs. Introversion), (2) information gathering style (Sensing vs. Intuition), (3) decision-making style (Thinking vs. Feeling), and (4) planning orientation (Judging vs. Perceiving). The MBTI highlights people's strengths and is commonly used in organizational settings for leadership development and to examine group dynamics. Although frequently used for occupational selection, its validity for this purpose is uncertain. Nonetheless, these dichotomies naturally relate to various career planning and work-related tasks. The authors of the MBTI stress that it can provide important insights into work motivations and approach to changes in the workplace. Numerous publications examine using the MBTI for managing careers.

The California Psychological Inventory (CPI) was developed by Harrison Gough in 1948 to emphasize normal personality using everyday language. It comprises 20 Folk scales that relate to four clusters of content including (1) interpersonal functioning, (2) normative orientation and values, (3) cognitive and intellectual functioning, and (4) role and personal styles. In addition, three broad scales, Internality-Externality, Norm Questioning-Norm Favoring, and Self-Realization, are compared to assign clients to classification types with career implications. There are 13 special scales, largely relevant to career counseling, including Managerial Potential, Work Orientation, Creative Temperament, Leadership, Law Enforcement Orientation, and Tough-Mindedness.

The Sixteen Personality Factor Questionnaire (16 PF) was developed in 1949 to assess 16 primary factors identified by Raymond Cattell's empirical analyses of personality traits. Some factors directly related to career counseling include Abstractedness, Dominance, Openness to Change, Perfectionism,

Self-Reliance, Sensitivity, and Warmth. The 16 PF also reports five broad scales assessing the Big Five, Holland theme scores, and four facets of leadership. A computer-generated career development report is available that addresses problem-solving resources, coping patterns, interpersonal styles, organizational role and work setting preferences, interests, and other lifestyle considerations. This profile also compares clients' scores with members of specific occupations.

The five Personal Style Scales of the Strong Interest Inventory include Work Style, Learning Environment, Leadership Style, Risk Taking, and Teamwork. These dimensions reflect personality features related to how individuals approach learning, work, and leisure.

### Building on Strengths

Among other activities, career counselors assist their clients in increasing self-understanding and in exploring career possibilities suitable to their self-concepts. These functions afford great potential for optimizing clients' work lives. Insights from personality theory, research, and assessment can facilitate this process through identifying relevant tendencies and nurturing clients' strengths. General personality assessments and those germane to career decision making have potential to help individuals seek goals that consider their inclinations, thereby allowing clients to strategically manage their careers and enhance their overall life satisfaction.

## PERSON–ENVIRONMENT FIT

---

Person–environment fit models are among the most widely used and influential models in vocational psychology. Ultimately, these models trace their lineage to Frank Parsons's suggestion that job outcomes could be improved by carefully matching the attributes of an individual with the characteristics of an occupation. In the 1930s, advances in statistics and psychometrics allowed Parsons's concepts to be operationalized using individual assessment and occupational classification systems, an approach known as *trait-factor counseling*. Overall, trait-factor counseling was criticized as being atheoretical, and its matching process as being too static. Current person–environment fit models, such as Holland's theory of vocational personalities and work environments and the theory of work adjustment, evolved from trait-factor counseling and represent fully fleshed and dynamic theories of career choice and adjustment.

There are a number of assumptions common to all person–environment fit models used in vocational psychology. These assumptions are (1) within an occupation, the well-adapted incumbents share certain psychological attributes; (2) there are measurable and practically significant differences between people and between occupations; (3) individual differences interact with occupational differences to positively or negatively affect outcomes; and (4) person attributes and occupational characteristics show sufficient consistency across both time and setting to justify the prediction of long-term outcomes. It is implicit in these assumptions that if workers and work environments can be reliably measured, then the quality of the match (or fit) between the two may be a useful predictor of outcomes ranging from job satisfaction to productivity.

## Historical and Theoretical Influences

The core concepts of person–environment fit models can be traced to a number of sources. As stated above, Parsons’s template matching approach and trait-factor counseling models were important influences on the evolution of person–environment fit models. Another important influence is captured in Kurt Lewin’s famous formulation of the interaction of person with environment:  $B = f(P, E)$ . Lewin proposed that behavior does not arise from a purely mechanistic interaction of person with environment, but rather it is influenced by the weight and value an individual gives to elements of the environment. Individuals bring unique learning histories to a given situation. These histories impact their interpretations and valuing of environmental features. Consequently, different individuals will behave differently given the same environment features. Another influence is found in Hans Selye’s conceptualization of stress as arising from a mismatch between organism and environment. In occupational settings, a mismatch between worker and workplace is expected to give rise to job dissatisfaction and/or poor job performance. It should be noted that person–environment fit models have been successfully applied to a wide range of behavior settings. However, applications to vocational psychology are the most sophisticated, both in terms of the variables assessed and the psychometric models used, and the most widely used.

## Subjective or Objective Environment Debate

As might be expected given the influence of Lewin’s field theory, many researchers working with person–environment fit models choose to assess the work environment as it is perceived by the worker. In keeping with Lewin’s thinking, it is argued that the *perceived* or *subjective environment* is what individuals are actually responding to in a given setting. However, it is important to note that some person–environment fit researchers reject operationalizing work settings subjectively for the very same reasons put forward by others arguing for its primacy. These researchers argue that because an individual’s perception of an environment is so colored by that individual’s unique learning history, the perceived environment is too variable and too subjective to be meaningfully applied

across groups of individuals. These researchers argue that the environment should be defined only by objectively determined and directly measurable attributes such as behaviors and physical features. Roger Barker’s behavior setting theory represents the best articulated and operationalized approach to the objective assessment of environments.

Many vocational models of person–environment fit fall somewhere in between subjective and objective measures of the environment. For example, the Environmental Assessment Technique defines environments in terms of the qualities (Holland types) of the individuals inhabiting a given setting. The theory of work adjustment defines individuals using self-appraisal methods, but categorizes work environments using pooled supervisor ratings.

## Measurement Assumptions

The choice of which person attributes and occupational characteristics to measure is challenging from both a theoretical and a psychometric perspective. For example, Holland’s career types have great intuitive appeal and seem to be supported by structural analyses. However, their exact configuration and perhaps more importantly their efficacy in predicting job satisfaction have been the topics of spirited controversy.

The following have been put forward as measurement assumptions for person–environment fit models: (1) the measurement of environmental characteristics and person attributes should utilize commensurate dimensions and units, (2) the level of measurement for the environmental characteristics and the person characteristics should be at least interval, and (3) the measurement of person attributes should be independent of the measurement of environmental characteristics. However, given current methods and measurement technologies, these assumptions represent ideals to aim for rather than goals attained.

## Assessing Fit

Ultimately, the crux of any person–environment fit model is how well it predicts relevant outcomes. This prediction is influenced by a number of factors: the assessment of the person, the assessment of the environment, the assessment of the outcome, how fit between person and environment is operationalized, and how fit is related (in a predictive manner) to

outcome. In vocational psychology models of person–environment fit, the assessment of the individual is generally well validated. As discussed above, the best method for assessment of the environment is not agreed upon. In vocational psychology, the outcome frequently measured is job satisfaction. When assessing global job satisfaction, this construct is robust enough that a single item is often used. However, it has been argued that job satisfaction is more meaningfully discussed in terms of its two facets—intrinsic and extrinsic job satisfaction. Depending upon the specifics of a given person–environment fit model, different fit indices may be possible and/or desirable. For example, fit indices for Holland’s theory of vocational personalities and work environments frequently factor in the hexagonal arrangement of the types. In addition, these indices typically weight for the relative importance of first, second, or third highest Holland types. In contrast, many of the fit indices proposed for use with the theory of work adjustment face problems classic to the quantitative comparison of psychological profiles. For example, difference scores, although simple to calculate, seldom can meet the measurement assumptions inherent in their use and perhaps more to the point tend not to perform any better than fit indices making less rigorous assumptions—that is, a correlation coefficient. Holland uses the term *congruence* to describe the fit between person and environment. The theory of work adjustment uses the term *correspondence*. Regardless of the fit index used, it is typically related to the outcome measure (typically, job satisfaction) using a correlation coefficient. Early literature reviews suggested that studies using Holland’s model had a relationship between congruence and job satisfaction of around  $r = 0.30$ . However, more recent reviews and meta-analyses have revised this figure ever downward with some arguing that the true value was in the 0.20s and with others that it was closer to 0.10. Similar studies using the theory of work adjustment have consistently found relationships of  $r = 0.30$  to 0.40 between correspondence and job satisfaction.

### Ongoing Influence

Although person–environment fit models have been criticized along similar lines as the trait-factor counseling approaches they grew out of, these models have been and continue to be very widely used. This use is due in part to the intuitive appeal of these models and

in part to the psychometric rigor that was devoted to developing both individual assessment instruments and occupational classification systems. Perhaps the strongest indication of the ongoing influence of person–environment fit models was the adoption of the core variables of Holland’s theory of vocational personalities and work environments and of the theory of work adjustment by the Occupational Information Network and the United States Department of Labor’s online database that is the successor to the *Dictionary of Occupational Titles*.

## PERSON MATCHING

---

One of the first and even now most-used tools of career counselors is the interest inventory. Inventories

currently in use may be described as taking either of two approaches. One tells a person the relative strengths of his or her interests; the other tells the person what occupations have similar interests as his or hers. The first approach reports, "Your interests are strongest in science." The other matches a person with occupations, reporting, "You have interests like those of engineers (or doctors, or other scientific occupations)."

Frederic Kuder, a long-time author of interest inventories of both kinds, speculated that a person can be similar to, say, an engineer, but in reality is more similar to a particular engineer engaged in a particular job. Kuder suggested replacing occupation matching with person matching. In the person-match approach, the interest inventory results answer the question "What are people with interests like mine doing for a living?" instead of offering an occupational title. As well, the inventory taker is presented with a number job sketches, reflecting what several people, not necessarily all engineers, who have similar interests as the inventory taker actually do every day. Kuder's assertion is that this should be more informative, and perhaps more motivating, to people seeking career options than a single occupational title.

Kuder and his associates developed the Kuder Career Search with Person Match to replace his Kuder Preference Record and the Kuder Occupational Interest Survey. Like the earlier interest inventories, it consists of triads of activities from which the respondent must choose the most and least preferred. Person matches are assessed by comparing the inventory taker's own interest profile with the profiles of approximately 2,000 adults in a wide variety of occupations using a mathematical rubric similar to those used for book purchase or movie rental recommendations.

The results of the Kuder Career Search are presented in two forms. One is a score profile in percentages of the relative strengths of six types of activity preferences. The novel Person Match report consists of the self-assigned occupational titles of a dozen members of the personal match pool whose interest profiles are most similar to that of the interest inventory taker. The inventory taker may open a self-reported, one-page job sketch from their top matches.

The job sketches are much like an interview. Questions are asked by the Kuder Career coach, such as, "What's a typical day at work for you?" "How did you get into this line of work?" "What are the positives and negatives in your job?" and "What are your

plans for the future?" Finally, the Kuder coach offers observations, pointing out unique aspects of the person's work or features of the person's career pattern.

Many persons would be well-served by learning of the careers of older individuals who have interests like their own: middle school students who are just beginning to make career plans, high school students who are selecting college programs, college students who are nearing graduation, older workers who are experiencing job displacement, and even retirees who are seeking to continue at work.

## PERSONS WITH DISABILITIES

---

Counseling interventions are considered a resource to support full functioning and participation of people with disabilities in their communities or specified environments of choice. The World Health Organization's (WHO) International Classification of Functioning, Disability and Health (ICF) considers disability to result from a person with a health condition's interaction with his or her environment where a person is restricted in his or her ability to engage in activities typical of others in the same or a similar environment. The functions of an individual with a disability are impaired by any disease, disorder, or health condition, and the severity of impairment contributes to the extent of disability or activity restrictions. The environment can enable or hamper participation. For example, an enabling environment for a person with mobility limitations would include access to mobility aids while, by contrast, environmental barriers

would include inaccessible buildings. Additional limiting factors such as negative attitudes, stigma, and power relations arise from social environments, and these factors often influence the organization of and delivery of support services. Persons with disabilities are restricted from activities typically open to others by environmental restrictions more than by the objective qualities of their specific disability. This raises the question whether persons with disabilities need counseling, and if they do, (a) what the rationale is for providing counseling services, and (b) what would the counseling address.

### Historical Considerations

Persons with disabilities are and have historically been denied recognition as a socioculturally oppressed minority due to the restrictions to activities and lifestyle ordinary to typically developing others. For instance, people with disabilities have limited access to basic social amenities compared to typically developing others because of negative social prejudice against them. They also tend to be socioculturally disadvantaged and ascribed negative characteristics because of their disability-related differences (e.g., incompetent, poor, suffering).

### *Sociocultural Deprivation*

Historically, people with significant disabilities were detained in institutions for (a) cosmetic reasons because they were considered an unpleasant sight from which persons without disabilities should be protected, (b) political reasons in the sense of their being denied basic humanness and citizenship, and (c) cultural reasons in the sense that their life experiences and needs were regarded too different from those of ordinary persons to warrant social concern. Acts of genocide were also committed against persons with disabilities in that they could be castrated without their consent and be denied the right to marry or procreate. Persons with disabilities have also been treated as commodities by charitable organizations, some of which made fortunes for their founders and directors by marketing the unmet needs of persons with disabilities. Counseling was rarely an option for this population about which there was considerable ambivalence regarding their role and function in the community.

### *Influence of Disability Rights Movements*

With the internationalization of civil rights for cultural minorities, persons with disabilities were perceived by the civic community, state, and federal governments to benefit from counseling that would enable their participation to the extent possible in typical activities and environments for others. Disability rights movements resulted in several national laws and international conventions to enable people with disabilities in their entitlement to equal and fair access to resources and a preferred life style. It may seem paradoxical that people with disabilities are regarded as in need of counseling when the evidence suggests that they are victims of societal oppression.

### Goals

Counseling may enhance a sense of personal and environmental control in people with disabilities by helping them (a) identify the particular goals they seek to achieve and the methods of achieving them, (b) access the resources in the environment that they may need in order to achieve their self-selected goals, and (c) learn more effective self-management skills. Counseling approaches for people with disabilities need to consider that disability is not an intrinsic feature of the individual, but the result of interactions with his or her environment. There are no universal counseling needs or processes that will address the counseling needs of people with disabilities in their diversity. However, the WHO ICF provided guidelines on functioning with disability, including types of domains of activity restriction and participation in nine areas of health and well-being.

### Guidelines

The WHO ICF guidelines enable identification of the disability-related type of activity or participation restriction, taking into account social and physical environmental factors. Some counseling professionals are of the view that the WHO ICF guidelines provide a practical framework for conceptualizing counseling needs in people with disabilities. For example, mental impairment from depression can restrict opportunities for beneficial interactions with others through self-isolation. Others may perceive self-isolation negatively, increasing the chances that the socially isolated

person will be avoided or rejected in the social environment. The cycle of social isolation and social rejection could spiral into a more severe depression, anxiety, learned helplessness, and passivity for which counseling would be a resource.

## Influences

The counseling needs of individuals with disabilities may also depend on the particular type of disability. A disability from a chronic, progressive condition such as renal failure presents unique counseling needs as compared to a stable disability like a healed and rehabilitated leg injury or amputation. The need for dialysis treatment associated with chronic renal failure often results in significant disruptions to routine or typical lifestyle and choices. Routine adds predictability to life by enhancing a sense of control over one's environment. Some disabilities are associated with chronic health conditions with unpredictable symptom expression, which would pose significant challenges to the way individuals manage their lives. For example, people with psychiatric disability may experience acute phases of severe symptoms and/or persistent symptoms of mental illness, and these symptoms tend to disrupt most aspects of their lives. Many face the additional challenge that stigmatizing attitudes of society presents. By comparison, a stable disability such as a healed amputation may present different kind of challenges. Thus, counseling needs in people with disabilities depend on the (a) effects or product of the interaction between personal, environmental, and disability-related characteristics; and (b) the relative severity of the environmental, disability, and personal factors.

## Future Directions

Counseling needs of people with disabilities are those whose resolution would enable them to have greater control over their lives. Specific counseling needs of individuals are influenced by the personal, disability type, and environmental characteristics, and often these characteristics are interrelated in their impact. The WHO ICF framework that considers disability in the context of personal, environmental, and disability type factors is particularly relevant to understanding counseling needs in people with disabilities.

## PREScreening, IN-DEPTH EXPLORATION, AND CHOICE MODEL

---

The prescreening, in-depth exploration, and choice (PIC) model, proposed by Gati and Asher in 2001,

provides a practical systematic framework for making career decisions based on decision theory. The PIC model consists of three stages: (1) prescreening the potential set of career alternatives to locate a small and thus manageable set of promising alternatives; (2) in-depth exploration of the promising alternatives, resulting in a list of a few suitable alternatives; (3) choice of the most compatible alternative, based on a detailed comparison between the suitable alternatives.

### Theoretical Background

Decision theory has been regarded as a potential frame of reference for career decision making for almost half a century. This perspective conceptualizes career choices in terms of the cognitive processes used to locate the career alternatives most compatible with the individual's preferences and capabilities. Career decision making is a complex task. The number and variety of alternatives is often very large, and many attributes (e.g., traveling, teamwork) are required for adequately describing the potential alternatives and the individual's characteristics. Therefore, comparing among the alternatives and evaluating their compatibility to the individual is a nontrivial task.

### The Three Types of Decision-Making Models

Three types of decision-making models have commonly been cited as potential theoretical frameworks for the career decision-making process. *Normative models* specify procedures for making optimal rational decisions, aimed at maximizing the subjective (expected) utility, based on an overall evaluation of the alternatives. *Descriptive models* focus on characterizing the ways individuals actually make decisions in real life and document biases and inconsistencies in individuals' natural decision behaviors that lead to less than optimal decisions.

*Prescriptive decision models* bridge the theoretically oriented normative models and the reality-oriented descriptive ones by providing a systematic framework for decision making while taking into account individuals' bounded rationality and intuitive thinking. Since it translates theoretical knowledge from decision theory into career counseling interventions, this type of model appears the most relevant for

facilitating career decision making. The PIC model is a prescriptive model that outlines a systematic and practical framework for making career decisions.

### The Three Stages of the PIC model

The PIC model aims at reducing the complexity of career decision making by separating the process into three distinct stages, each focusing on a well-defined task: prescreening, in-depth exploration, and choice.

### Prescreening the Potential Alternatives

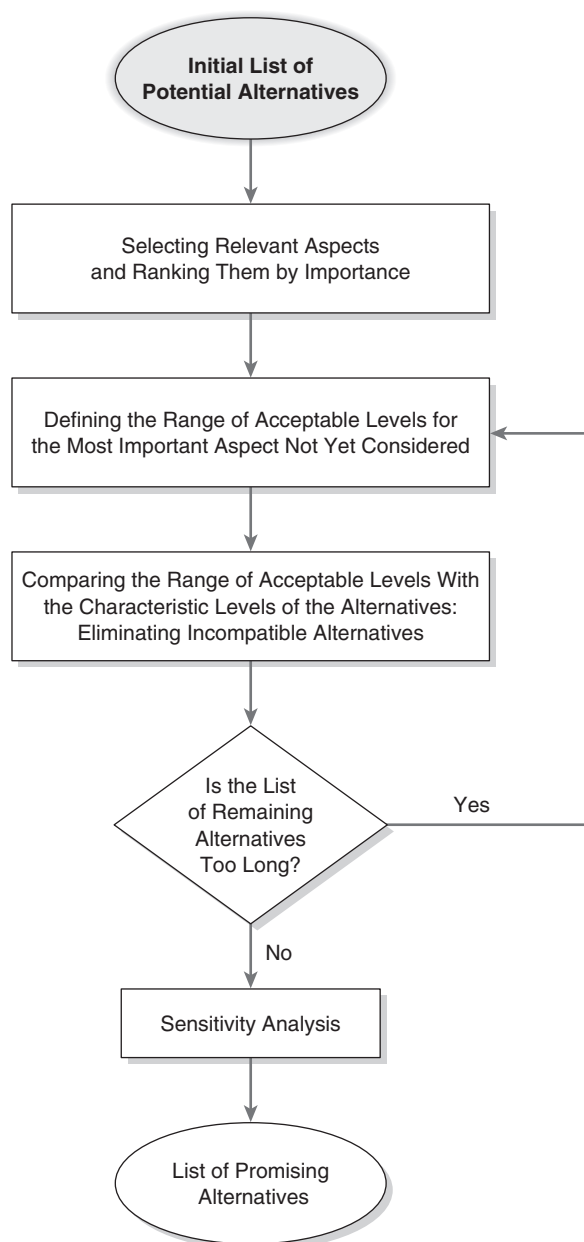

The goal of the prescreening stage is to deal with the overload of information in career decision making by helping the individual focus on the most relevant information. The goal is to locate a manageable set of promising alternatives that deserve further, in-depth exploration, using *sequential elimination*. The idea of sequential elimination is based on Tversky's 1972 elimination-by-aspects model, which has been shown to be compatible with the intuitive ways individuals make decisions when faced with a large array of alternatives.

The search for promising alternatives is based on the individuals' preferences in career-related aspects that are most important to them. *Career-related aspects* are all variables that can be used to characterize either individuals' preferences and abilities or career alternatives. The list of important aspects that should guide the prescreening process includes objective constraints (e.g., disability), competencies (e.g., creativity, technical skills), and core preferences (e.g., teamwork). The model distinguishes among three facets of the individual's preferences: (1) the importance of the aspect, (2) the level regarded as optimal (e.g., "only outdoors"), and (3) additional, less desirable but still acceptable level(s), representing the individual's willingness to compromise (e.g., "mainly outdoors").

The process of sequential elimination is a within-aspect, across-alternatives search: It is conducted aspect by aspect, starting from the most important one. For each aspect, the characteristics of all potential alternatives are compared with the individual's preferences, and incompatible alternatives are eliminated. The process is repeated for the remaining aspects in descending order of importance until the number of remaining promising alternatives is manageable (i.e., seven or less). To decrease the possibility that potentially suitable alternatives might be eliminated

because of a minor mismatch, the prescreening stage ends with a reexamination of the effects of potential changes in the individual's inputs on the outcome—the list of promising career options; this process is called *sensitivity analysis*. These steps are summarized in Figure 1.

**Figure 1** The steps of the prescreening stage

Source: Adapted with author's permission from Figure 1 in Gati, I. (1986). Making career decisions: A sequential elimination approach. *Journal of Counseling*, 33, 408–417. Copyright by the American Psychological Association.

### *In-Depth Exploration of the Promising Alternatives*

The goal of this stage is to confirm that a promising alternative is indeed suitable for the individual. During this stage, the analysis focuses on a within-occupation, across-aspect evaluation. This involves zooming in on one promising alternative at a time and collecting additional, comprehensive information on it to find out (a) whether the occupation is indeed compatible with the individual's preferences, (b) whether the individual is willing and able to satisfy the demands involving the essence of the occupation (i.e., its core aspects, e.g., physical treatment of people and working in shifts for a paramedic), and (c) the probability of actualizing that choice, taking into account the prerequisites of the occupation and the requirements for success in it. During this in-depth exploration, some promising alternatives will be eliminated, and thus this stage will end in a short list of suitable alternatives.

### *Choice*

The goal of this stage is to choose a few most suitable alternatives, rank ordered by priority of implementation. It involves a refined, detailed comparison between the alternatives under consideration, focusing on the differences among them. The small number of alternatives still relevant at this stage makes it possible to use the principles of rational normative models, and in particular the principle of compensation (i.e., trade-offs between the advantages and disadvantages of each alternative). The process that can be advocated is based on comparing pairs of alternatives from the short list of final options. It involves canceling out the relative advantages of the compared alternatives in each pair until the decision maker remains with only the net advantages of one of the alternatives. This process is repeated until only one alternative remains. Finally, the congruence between the outcome of the systematic decision process and previously intuitively appealing occupational alternatives should be examined: it may strengthen the individual's confidence in the choice or indicate the need for a reexamination of the decision process in order to locate the sources for incompatibilities and try to reconcile them.

## Research Findings

Research has supported the rationale underlying the PIC model and its descriptive validity. It has shown that individuals' information-seeking behavior is compatible with the stages of the PIC model. Specifically, when faced with a large array of career options, people tend to use a small number of significant criteria, one at a time, to reduce the number of alternatives to a few; but when faced with a small number of alternatives, people can compare them using compensatory principles. Interventions based on the PIC model, such as MBCD (an Internet-based career planning system; ), has demonstrated its effectiveness: (a) decreasing individuals' career decision-making difficulties, (b) helping them advance toward making a decision, and (c) increasing the probability of greater occupational satisfaction in the future.

## Using the PIC Model in Career Guidance and Counseling

The role of career counselors includes guiding clients through the stages of the decision-making process while encouraging them to play an active and dominant role in each stage. During prescreening, career counselors should help clients explicate their preferences (and their willingness to compromise, if needed), and take notice of actual or perceived constraints. During the in-depth exploration, counselors should direct clients to relevant sources of information, highlighting the quality of various sources in terms of accuracy and biases. During the choice stage the counselor can assist the client through the complex task of evaluating the suitable alternatives. Finally, counselors can guide clients in exploring ways to increase the probability of actualizing the most preferred alternative. The PIC model can serve as a framework for a dynamic counselor–client dialogue as well as for monitoring the client's advancement in the process. In addition, PIC can serve as a blueprint for designing computer-assisted career guidance systems, such as MBCD.

## Future Directions

Dealing with career indecision has long been a focus of theory and research, and helping clients to overcome their indecision is among the core roles of career counseling. The PIC model demonstrates the

potential in adopting decision theories for designing interventions aimed at fulfilling that role. However, there is still a need to reinforce the mutual enrichment between theoretical knowledge about decision making and the hands-on experience of career counselors. Future efforts to combine the normative and descriptive models for career decisions are likely to yield a more comprehensive prescriptive approach for facilitating the career decision-making process. The challenge is to design systematic guidelines that allow adaptive and active career decision making in the face of uncertainty, fuzziness, and change that characterize the 21st century's world of work.

## PRIVATE PRACTICE CAREER COUNSELING

---

Career counselors working in private practices typically provide services to individual and organizational clients. The services most often rendered to individuals include assistance with career decision making and planning, coaching, and securing employment. Organizations most often retain private practitioners to assist with staffing decisions, developing succession plans and programs, and outplacement.

Many career counselors' private practices evolve and are market driven. Some have, for example, developed specialized practices related to corporate employment selection (evaluating candidates being considered for new hire or promotion), partner relocation (assisting "trailing partners" in dual-partner relationships with career transitions after their partners' job transfers necessitated relocation), and forensic expert services (providing analyses in disputes related to earning capacity). A counselor's talents and interests—along with local market needs and other business factors—typically shape the complexion a private practice assumes.

Private practice services are rendered on a fee-for-service basis and in addition to providing services counselors operate for-profit businesses. Since a practice's viability depends upon a counselor's ability to consistently maintain a business volume that generates fees higher than costs while also allowing the counselor to realize compensation goals, private practitioners must be astute businesspeople. As in any business, the delivery of quality services, marketing, pricing, operations management, and other business functions are central to private practice success. Simply put, a private practice career counselor must be skilled technically, professionally, and entrepreneurially.

Because private practitioners must be competent businesspeople and have experience in a for-profit business, preferably in a consulting organization, business-related training is also recommended. Most career counselors transition into full-time private practice via part-time initiatives, after having maintained another, allied, source of employment. They then transition into full-time private practitioners as their practices become established. This helps minimize risk and enables practitioners to adapt resources and business development strategies as market factors

are tested. A sound business plan, with ongoing refinement, is essential to career counselors considering private practice venues.

Clients who seek private practitioners' services can greatly benefit from specialized, on-demand, and individualized career development assistance—provided a competent, ethical practitioner renders the services. Many unqualified individuals, however, purport to offer quality career guidance services. Consumers are cautioned to conduct due diligence before engaging a private-practice career counselor. The National Career Development Association maintains guidelines to help consumers select appropriate services and to understand standards of practice essential to effective service delivery.

## PROCESS AND OUTCOME RESEARCH

---

Process and outcome research are two interconnected research methodologies that identify the processes that go on in counseling sessions and the effectiveness of these processes in outcomes for clients. Specifically, process research identifies the counseling variables involved in client change, while outcome research identifies the actual changes that occur.

Moreover, following the definition of psychotherapy process, *career counseling process* denotes the overt and covert thoughts, feelings, and behaviors of both the client and the counselor during a career counseling session. *Outcome* denotes changes that occur directly or indirectly as a result of career counseling as measured in terms of immediate effects, intermediate effects, or distal effects.

Within process and outcome research, there may be several process variables that are contributing to the outcome of the client. Process and outcome research is necessary in career research because career counseling involves psychological and emotional components that require counselors to use many of the same therapeutic skills that are used in psychological counseling. Thus, the majority of research designs and process and outcome variables of interest in career counseling are parallel to those investigated in personal or therapeutic counseling.

### **Process Research in Career Counseling**

Process inquiry may include both the covert and overt variables of therapists and clients (such as thoughts, feelings, and behaviors) that take place in a counseling session or over the course of several sessions. Process career research has been conducted through the use of two major approaches: naturalistic settings and analogue inquiry. Naturalistic settings are actual counseling sessions with real clients. Forms of naturalistic inquiry include case study (e.g., a detailed focus on one or a few clients to identify process variables), conversational analysis (e.g., analysis of conversation between therapist and client to identify process variables), client's expectations about career counseling, and process variables in group career counseling. Analogue inquiry involves the use of artificially created counseling situations to identify process variables. Analogue research usually involves watching a videotape of a mock session or reading a transcript that resembles an actual counseling session. Most analogue research has focused on counselor variables that may influence the process, such as verbal responses or behavior. Analogue inquiry has examined such variables as counselor verbal responses, counselor in-session behavior, and the process variables in initial interviews. Naturalistic settings allow the researcher to easily generalize findings about the career counseling process, but offer the

researcher little control over confounding influences on process variables being measured. While analogue research allows a greater control over the processes being measured, the results are also more difficult to generalize to other individuals outside of the study.

There are four major design decisions that have been identified in the literature that will determine the format of the process research inquiry: (a) what specific processes are being measured, (b) the number of counseling session(s) that will be used to examine the specific processes, (c) the perspective or vantage point from which the specific processes will be measured, and (d) how the gathered data on processes will be evaluated. While there are many processes occurring during a counseling session (e.g., the formation of the working alliance between the counselor and the client), the researcher determines which specific process variables will be focused on and measured, as well as the level on which they will be measured. Examples of focuses of specific processes include content of session(s), what is done in session(s), style of session(s), and quality of the session. This focus may be measured on the microlevel (words stated) to the macrolevel (counseling relationship). For both naturalistic and analogue settings, most process research utilizes trained raters who identify and code the processes of interest taking place in the counseling session(s), thus providing a vantage point of how processes are measured. Traditionally, process data analyses have been correlational, but it is possible to use other forms of statistical analyses.

### **Outcome Research in Career Counseling**

Outcome research seeks to evaluate the effectiveness of specific career interventions or general career counseling services. Outcome inquiry measures the effects of career counseling or interventions by comparing different career interventions to each other and to control groups. In career counseling, effects are measured by comparing (a) individual counseling to group counseling, (b) brief counseling to long-term counseling, and (c) career counseling to control groups. The effects are identified through the use of quantitative instruments that measure specific outcome criteria. Outcome criteria are variables that indicate the amount of change in a specific area—such as client satisfaction, realism or career choice, and career self-efficacy—as a result of the provided career service.

Outcome criteria data may be measured while a client is still in counseling, after counseling has been completed, and during a follow-up measurement.

Increasingly fine-tuned meta-analyses have been conducted over the past 2 decades that demonstrate that effect sizes of career counseling varied, with some studies indicating it to be as high as .87 and others as low as .41. These varying effect sizes have prompted researchers to call for more thorough inquiry into career counseling as an intervention specifically and to examine a range of potential outcomes. Although it is important to know that most studies indicate that career counseling is effective with most clients, most of the time, learning more about the particular mechanisms that lead to positive outcomes is a critical research area.

As with process research, the researcher determines which outcome criteria to measure and selects appropriate instruments for this measurement. The outcome measures, or effects of career counseling, are highly influenced by the methods used in the study. Career outcome research utilizes both recruited participants who are given career counseling for the sole purpose of measuring outcome and actual clients who are receiving career counseling services. As with outcome research in personal counseling, not having random assignment and a control group will inhibit the researcher's ability to attribute the measured effects to career counseling. Thus, within career counseling research the utilization of actual clients and comparison control groups is recommended for greatest ability to measure outcome effects.

### Combined Use of Process and Outcome Research in Career Counseling

Process and outcome research have not been conducted in career counseling to the same extent as in psychotherapy. This lack of process career counseling research has been highly influenced by the former view that career counseling is void of psychological elements and thus not in need of process information.

In addition, career counseling is generally viewed as being effective, a view that does not prompt researchers to spend time conducting labor-intensive process inquiry that breaks down known effectiveness element by element. Outcome research is essential for career counseling because it has the power to measure the specific effect career counseling has on clients, while process research identifies the mechanisms taking place in career counseling that lead to that outcome. Recently a research agenda has been outlined in order to guide researchers to more systematic inquiry into the process and outcome of career counseling.

## RETIREMENT

---

Modern life can be viewed as calling for a predictable series of developmental stages. Donald E. Super, a vocational psychologist, has identified five, each one named for its main activity: growth, exploration, establishment, management, and disengagement. Development through these stages requires a series of transitions: from childhood to school, from school to employment (and/or marriage and parenthood), then to increasingly responsible jobs, and finally to retirement.

Up until the 20th century, the notion of retirement as we now know it hardly existed. Most people simply worked until they could not anymore. But in the early 1900s, certain occupations—teachers, municipal workers, and especially police officers and firefighters—sought mandatory retirement and benefits. In 1935, the U.S. Federal Government passed the Social Security Act, which paid benefits to all workers who had reached the age of 65. (The actual law and its modifications since that time are greatly more complex than this simple statement.) At that time there were about 7 million men and women age 65 and older. In 2000, the number was closer to 35 million. Presently, the population surge of retiring baby boomers will swell this number. Clearly, retirement has become a significant aspect of modern life.

There are a number of issues to be considered in the transition to retirement. Finances typically receive serious attention, since for many people retirement means reduced income. Health, complicated by the simple process of aging, is probably the second-ranking retirement issue. Another issue that is gaining attention

is use of time—the opportunity to do whatever one wants: traveling, grandparenting, renewing old hobbies, volunteering, continuing education, and even a new career, among other things.

Counseling Psychologist Nancy Schlossberg has studied retirees and sees coping with the retirement transition as depending on a number of variables: financial security and health, of course, but also the role that employment and careers has played in the life of the individual and his or her family, at what age one retires, whether the individual has liked his or her career, and the degree of planning for retirement, among many others.

More importantly, Schlossberg has found a number of ways of dealing with retirement. Among them is one she calls “continuers,” which is Schlossberg herself, who exchanged her professorship in adult and career development for her present role as a retirement transition facilitator. Another role is the “easy glider,” who doesn’t plan, but simply lets each day of retirement unfold. There are also “adventurers,” who start entirely new activities—a new career, a commitment to a volunteer cause, earning a degree that was not achieved earlier, researching one’s family history, and the like.

Overall, the transition to retirement merits careful thought and attention to possibilities—and opportunity for the counseling profession.

## ROE, ANNE (1904–1991)

---

Working at a time when few women were active as researchers, Anne Roe provided a different perspective on career choice and adjustment and is now credited as being the forerunner of a psychodynamic perspective. Roe was particularly interested in individual psychological differences between people and utilized research and statistical methods. From the 1930s, she engaged in a range of clinical psychology research, for example, in investigating intelligence and learning disability, the correlates of alcoholism, the personality of artists, and the psychology of creativity. This diversity and working separately from the mainstream of counseling psychology enabled her to approach the topic of career choice in a fresh way.

In 1956, she wrote *The Psychology of Occupations*, which outlined her understanding of the role of occupations in both society and individual lives, early experiences and their influence on career patterns, and occupational groups. This work evolved from a systematic study of well-known research scientists and artists, where she gathered extensive retrospective developmental accounts to enable her to identify factors involved in career choice. The book publicized the two main strands of her theorizing about careers: the classification of occupations and the origins of career needs and interests.

Roe sought a scheme for categorizing occupations and was dissatisfied with those in existence because they were lists rather than being underpinned by an organizing rationale. She therefore considered research that had used factor analysis and developed eight occupational groups titled service, business contact, organization, technology, outdoor, the sciences, general culture, and arts and entertainment (labeled as groups I–VIII). Roe postulated that the first three and last two groups were careers orientated toward people, whereas groups IV, V, and VI were more orientated

away from people. She arranged these eight groups into a circle rather than into a list. She developed this work further by suggesting six levels of occupation depending on level of responsibility, aptitudes, and skills, which she represented as layers below the circle (in a cone shape). Level 6 (the lowest) represented unskilled jobs that she believed were less differentiated than the higher levels, with level 1 representing professional and managerial jobs. Her classification groups were used both in many practical applications (e.g., to develop interest tests, group college programs, and as a basis for careers education) and generated research into a number of aspects (e.g., career aspirations of high school pupils, occupational change, and sex-role stereotyping).

Roe's ideas about the links between occupational choice and developmental (especially parental–family) determinants have led to extensive debate in the field, with limited research support. Roe focused on the influence of personal experiences of varied parental attitudes in the early years to propose the individual channeling involuntary attention toward people or toward other phenomena. She believed that the degree to which parents concentrated emotions on the child (being overprotective or overdemanding), accepted (in either a loving or casual way), or avoided the child (via emotional rejection or neglect) determined the way in which the child's subsequent needs and interests would be channeled and affected communication and organizational skills.

Over a number of years, Roe and her associates developed two versions of the Personal-Child Relations Questionnaire to enable parental attitudes to be investigated, leading to scores on scales (two bipolar and one unipolar): loving–rejecting, casual–demanding, and overt attention. The complexity of differences in influence between two parents, differences over time, differences depending on sex of parent and child, and the limitations of retrospective accounts have all had an impact on the challenges of using this approach in career counseling. Roe herself acknowledged that her theories were less applicable to the complexities of women's and minority groups' career development. Many career counselors credit Roe with highlighting of familial determinants and considerations of life history in career choice processes. In her later work, she devised a formula that was inclusive of a wider range of variables that enter career choice processes and allowed for the shifted weighting of these over the life span.

## ROE'S THEORY OF PERSONALITY DEVELOPMENT AND CAREER CHOICE

Anne Roe (1904–1991) was born and raised in Denver, Colorado. Upon graduating from the University of Denver, she attended Columbia University, following the recommendation of Thomas Garth. At Columbia, Roe worked in the office of Edward Lee Thorndike, graduating with her Ph.D. in experimental psychology under the supervision of Robert S. Woodworth. The publication of *The Psychology of Occupations* would introduce Roe's theory of personality development and career choice, her most enduring scientific contribution.

Roe's theory can be separated into two key areas: theoretical aspects of personality and classification of occupations. Inspired by Maslow's hierarchy of needs, Roe incorporated the psychological needs that develop out of parent–child interactions in her conceptualization of personality. Roe classified parent–child interaction patterns into three categories, each with two subcategories: (1) emotional concentration on the child, further classified as being overprotective or overdemanding, (2) avoidance of the child, further classified as emotional rejection or neglect, and (3) acceptance of the child, further classified as casual or loving. Roe's interest in parent–child interactions

led to the development of the Parent–Child Relations Questionnaire and its revision as a means of accurately assessing such interactions. Out of parent–child interactions, Roe thought that children went on to develop an orientation either toward or not toward people.

Roe was dissatisfied with existing classification systems for occupations, including the benchmark *Dictionary of Occupational Titles*. In order to compare the individual to a full spectrum of occupations, Roe set out to develop a comprehensive classification system that would allow her to engage her inquiry. The result was a two-dimensional, eight by six classification system with eight categories of occupations (service, business contact, organization, technology, outdoor, science, general culture, and arts and entertainment) and six levels (professional and managerial, levels 1 and 2; semiprofessional and small business, level 3; skilled, level 4; semiskilled, level 5; and unskilled, level 6) within each category.

Research into the impact of parent–child interactions on career choice has not resulted in significant support for Roe's theory. Concerns with subject recall of parent–child interactions, differences in parenting styles between parents and over time, and sample sizes, among other issues, have been cited. Roe openly acknowledged the criticisms of her theory and expressed concerns that her classification system did not adequately address the experiences of women and minorities. In addition, Roe stated that her theory was developed with little forethought in regard to its application. Still, research support can be found for Roe's classification system, and a minimal amount of support has been found related to the impact of early interactions upon the work-related behaviors and activities within certain areas of occupational specialization. The impact of Roe's theory has been realized across the various facets of activities of career development professionals such as teaching, counseling, placement, and research. Roe's classification system has proven particularly useful to career counselors in the influence it has had in the development of career assessment instruments and in its overall contribution to the mapping of the world of work.

## SCHOOL-TO-WORK TRANSITION

---

Most people will encounter the developmental task of making the transition from school to work, as the assumption of the worker role is one of the hallmarks of adulthood. However, the school-to-work transition generally refers to the transition made by those youth who are moving directly from high school to work, frequently with minimal support. Because it is a part of the adolescent-to-adult transition, the move from school to work presents the individual with several challenges and opportunities. Because it is integral to the mission of the central social institutions of education and employment, the school-to-work transition is also a major policy and reform issue.

### **School to Work as a Developmental Transition**

Transitions of any type bring with them periods of uncertainty and stress. In the transition from school to work, that stress is exacerbated by the fact that work is necessary to meet basic survival needs. In the United States, youth who do not attend college are more likely to be unemployed or to be employed in transient jobs with little opportunity for advancement. The lack of a college education results in significant decreases in lifetime earnings as well. These issues are particularly problematic for youth who are African American, Hispanic, and American Indian, all of whom have substantially higher unemployment rates, lower college attendance rates, and lower high school graduation rates than do White Americans.

A primary task of this time of transition is to develop the skills necessary to be an effective worker. Historically, this has involved learning specific skills related to trades or occupations and then moving into an entry-level job for which one has specifically prepared, similar to the training of an apprentice. However, in the current labor market, occupation-specific skills are often not as critical as transferable work skills. Employers report that they are seeking workers with broad skills in reading, writing, math, and communication (listening and speaking); the ability to work well with others, be creative, solve problems, and be organized; and an attitude of responsibility, self-management, and integrity.

This set of skills provides a foundation from which potential employees can learn job-specific skills more readily. It also emphasizes the need for career counselors to prepare students to be work ready rather than job ready. This need is reinforced by the reality that most people will change jobs multiple times over the course of their lives, leading many career theorists to point out that the most important task of career counseling may be to prepare young workers to be adaptable to changing labor and market demands. Essentially, the task of this developmental transition is to assume the skills and attitudes necessary to negotiate a rapidly changing work environment.

### **School to Work as a Policy and Reform Initiative**

In response to a landmark report published in 1998 by the William T. Grant Foundation, *The Forgotten Half: Pathways to Success for America's Youth and Young*

*Families*, educators and policy makers began to look closely at the needs of work-bound or noncollege-bound youth and determined that the school-to-work transition in the United States was in significant need. In fact, former U.S. Secretary of Labor Ray Marshall remarked, in the early 1990s, that America had the worst school-to-work transition process of any of the industrialized nations. In contrast to other countries, particularly in Europe, that provide structured apprenticeship models to transition youth into work, the United States has very few services in place for work-bound youth, resulting in longer periods of struggle with part-time, low-paying jobs. In fact, work-bound youth receive approximately 10% of the values of services that college-enrolled youth receive.

Policy efforts to address the concerns raised in *The Forgotten Half* resulted in federal legislation, the School to Work Opportunities Act (STWOA) of 1994, that codified several major components of school-to-work programs. The STWOA provided block grants for states to design school-to-work programs that included the following components: school-based learning, workplace-based learning, an integration of the two through coordinated efforts between teachers and employers, and stakeholder support in the form of parents, community groups, employers, and other concerned parties. From these grants emerged a number of types of school-to-work programs, including tech preps, career academies, occupation-academic cluster programs, school-based enterprise, cooperative education, and youth apprenticeship programs. The initiation of STWOA programs was not without controversy, however. Several states ultimately passed laws that banned or modified school-to-work programs as described in the federal guidelines.

Evaluations of the federally funded school-to-work programs have provided mixed findings. Several evaluations of single programs (i.e., programs in a single school district) have suggested that students who participate in a school-to-work programs are more likely to earn better grades, complete more high school credits, and attend college than those who do not participate. This finding has been more robust for boys than it has been for girls. Large evaluation studies of the impact of STWOA legislation have suggested that only a small number of students have actually been able to complete the linked school-work activities that STWOA intended to provide. However, there is also evidence that participation in work-related activities did increase among work-bound youth who participate in school-to-work programs.

## Effective School-to-Work Programs

Several challenges to establishing effective school-to-work programs have been identified: workplace learning requires significant support from school staff, accompanied by expense to the schools; employers who are willing to assume some of the costs for school-to-work programs may not benefit if participants decide to go on to college, thus reducing employer motivation to participate; and workplace activities and academic success sometimes conflict with each other, particularly in terms of time demands.

Successful school-to-work programs have several characteristics that allow them to address these challenges. First, they gather input from a number of local constituents, including employers and parents, to meet the needs of local students. Second, school personnel are invested and the program is integrated into the school environment. Similarly, employers who are invested early are more likely to continue as partners, even if some students do not remain on as full-time employees. Finally, there is some indication that beginning career activities early in elementary school contributes to greater success, as does developing a school-work curriculum that is strong enough to prepare participants for both 2- and 4-year colleges.

## Future Directions

Although legislative attention to the school-to-work transition and the needs of work-bound youth has diminished, the needs of the population remain significant. For example, work-bound youth continue to earn significantly less income than do those who go to college. The U.S. Census Bureau reported in 2005 that the mean income for earners of the bachelor's degree was \$51,206, those with high school diplomas earned \$27,915, and those who did not graduate from high school earned an average of \$18,734. Furthermore, the Economic Policy Institute reported that approximately 33% of workers with a high school diploma were not covered by health insurance in 2005, compared to approximately 18% of those with college degrees.

Of course, economic outcomes are not the only evidence of work or career success. Nonetheless, these indicators make it clear that greater attention must be paid to a successful school-to-work transition for youth who are most likely to be disadvantaged and are ultimately most likely to stay in a less advantaged state as they mature. Continued attention to career and vocational education, leading to the development of

effective work readiness strategies, is essential to meaningful education reform and to the well-being of workers in the United States.

## SELF-DIRECTED SEARCH

---

The Self-Directed Search (SDS) is an interest inventory based on John Holland's RIASEC theory that people, work, and educational environments can be classified according to six basic types: Realistic, Investigative, Artistic, Social, Enterprising, and Conventional (RIASEC). According to the SDS's publisher, Psychological Assessment Resources, Inc., the SDS is the most widely used interest inventory in the world and has been translated into 25 languages. The SDS helps individuals identify occupations and fields of study that best match their self-reported interests and abilities. The SDS is based on the assumption that individuals whose job and work environments closely match their personality and interests usually consider themselves satisfied and successful with the career choices they have made.

The most commonly used version of the instrument is the SDS Form R (SDS R). In the Form R *Assessment Booklet*, individuals list their occupational aspirations in the Daydreams section, which can be scored separately to generate a daydreams summary code, or expressed interest code. Users are initially asked to review the *Occupations Finder* to locate a three-letter RIASEC code for each occupation listed, which immediately engages them in an occupational exploration activity. Additional sections include self-ratings of activity preferences, competencies, and occupations. In the last section, users rate their abilities across the six RIASEC areas. The SDS R has a self-scoring system that produces a three-letter summary code. The summary code, also called the assessed code, reflects the three RIASEC personality types an individual most closely resembles.

The SDS is a stand-alone career planning simulation that imitates an interest inventory, as well as a psychological test. The original paper and pencil SDS R has been revised 4 times, most recently in 1994, and includes the *Assessment Booklet*, the *Occupations Finder* (1,335 occupations employing 99% of U.S. workers and updated with additional information technology and Internet occupations in 1999), and the

*You and Your Career* booklet, which includes a brief review of scientific ideas supporting the SDS, guidelines for interpreting scores and codes, the personality characteristics associated with each RIASEC type, and some suggestions for successful career planning. Normative data for the 1994 edition of SDS R can be found in the *Professional User's Guide and Technical Manual* available from the publisher.

Although most counselors are familiar with the SDS R paper version, the other varied SDS formats and versions are less widely known. A computer-based version of SDS R provides for faster administration and more efficient use of the inventory. The computer generates a 10- to 12-page Interpretive Report for users based on SDS summary scores and a 1- to 3-page professional summary for counselors that includes additional diagnostic information. A sample report is available at [www.self-directed-search.com](http://www.self-directed-search.com).

Besides these various formats of SDS R, other versions of the SDS include Form E (Easy) for persons with poor English language or reading skills, Form CP (Career Planning) used with adults working in organizations, and Career Explorer designed for middle school students. These alternative formats of the SDS have the same basic features of SDS R. An Internet version of the SDS is also available, but it omits the Daydreams section, and there is no professional summary generated. The Internet version can be accessed at [www.self-directed-search.com](http://www.self-directed-search.com). In addition, as noted previously, the SDS is available in many other languages including French, Icelandic, Japanese, Korean, Spanish, Vietnamese—to name a few.

## Using the SDS in Practice

### **Expressed Interests**

From the very beginning, Holland urged counselors to pay close attention to what persons say about the occupations they are considering. Specifying occupational goals has been shown to be very predictive of a person's future occupational activity, in some cases achieving the prediction rate of assessed interests obtained from various standardized inventories.

An important innovation in the measurement of aspirations in the SDS Daydreams section was the coding of a person's occupational daydreams using the RIASEC typology. This procedure enables a counselor to examine not only the occupation named, but also its RIASEC code. When the first two or three

aspirations belong in the same RIASEC category, the predictive power of the first aspiration equals or exceeds the efficiency of an interest inventory.

### **Assessed Interests**

The SDS has been described as a simulated career planning experience because it reflects what might actually happen when a person is interviewed by a career counselor. For example, it is not uncommon for career counselors to ask individuals seeking career assistance, "What do you enjoy doing?" "What kinds of things do you do well?" and "What occupations have you thought about?" The *SDS Assessment Booklet* sections provide a way for counselors to observe how persons view themselves and their prior experiences in relation to their current educational and career decision making. The SDS is also a standardized career assessment instrument. The items in the *Assessment Booklet* have desired psychometric properties and are based on Holland's RIASEC theory. The SDS has been subjected to the same rigorous test development standards as other professionally published tests, and the SDS manuals describe a complex, theory-based test development process begun in 1970.

The Activities section of the SDS R *Assessment Booklet* has 11 items for each of the six RIASEC types. The items cover activities and hobbies that are done for fun or leisure, and users can endorse them as *like* or *dislike*. These items are included in the SDS because they effectively measure interests in relation to RIASEC theory.

In the Competencies section, users describe their skills, the kinds of things that they learned to do in the past, and indicate the skills they might want to develop in the future. This kind of information is practically important because it is reasonable to assume that persons completing a career assessment will want to consider their prior skills and accomplishments, as well as future skills they hope to develop. The Competencies section of the SDS R includes 11 items that are marked *yes* or *no* for the six RIASEC areas.

The next section of the SDS R is Occupations. It is longer than the previous two sections and includes 14 items (occupational titles) that are endorsed *yes* or *no* for each RIASEC area. Holland included this section because he wanted to make sure he obtained a good measure of the person's RIASEC typology and because he wanted to get a sense of a person's likes

and dislikes with respect to various occupational titles.

The final section of the SDS R *Assessment Booklet* is Self-Estimates. It includes the six RIASEC scales, which are rated twice (from 1 to 7) with respect to ability and skill. Users are asked to rate themselves “as you really think you are when compared with other persons your own age.”

### Implications

When the SDS was initially introduced, some critics scoffed at it and called it simplistic. More recent reviews have noted that the use of Holland’s inventories is extensive. The SDS is unique in several ways: (1) it is self-administering, self-scoring, and self-interpreting; (2) it is based on Holland’s theory; and (3) it is supported by extensive research studies numbering more than 500. The SDS is an inventory with well-documented psychometric characteristics that incorporates a person’s history of vocational daydreams or expressed interests, which in comparison to the assessed results can be used to increase predictive validity about the person’s future occupational choices. Because it is self-scored and can be easily interpreted by most users, it encourages a person’s active participation in the resolution of career problems and questions. After completing the SDS, individuals know more about themselves, more about occupations, and more about how to think about occupations in relation to their personal characteristics, thus gaining a framework for immediate career decisions and future occupational exploration.

## SEXUAL HARASSMENT

---

Sexual harassment remains a common occupational hazard for women. It is estimated that over half of all women will experience some form of sexual harassment during college and/or their working lives. Women in male-dominated workplaces, in blue-collar jobs, or who are marginalized due to their race, sexual orientation, or social class often experience higher rates of sexual harassment than the general population. Although the vast majority of all sexual harassment cases involve men harassing women, there are also cases of men being sexually harassed. These cases usually involve same-sex harassment, where a man is targeted as a form of hazing or for perceived violations of hypermasculine gender role stereotypes.

Sexual harassment is both prevalent and harmful for targets and the organizations within which they work. Once harassed, individuals, whether male or female, report a variety of negative outcomes related to their work, health, and psychological well-being. Across a spectrum of outcome measures, harassed men and women fair more poorly than those without a history of harassment. Specifically, research has documented detriment to the job satisfaction, work productivity, supervisor satisfaction, absenteeism, and turnover rates of harassed employees—the costs of which can reach billions of dollars annually for federal and private institutions. The psychological and health-related costs are equally high, with targets

reporting numerous symptoms, such as depression, posttraumatic stress symptoms, and health problems following harassment. Despite the contributions of individual and sociocultural factors, organizations have many strategies at their disposal to reduce the prevalence of sexual harassment within their institutions. These efforts will not only protect employees from the harm of harassment, but also limit employers' legal liability. Ultimately, an equitable work environment that is free of harassment benefits everyone within the institution.

### Definitions

In 1980, the Equal Employment Opportunity Commission identified sexual harassment as a form of sex discrimination that commonly manifests as either a *hostile work environment* or *quid pro quo*. Hostile work environment refers to an environment where sexual harassment is pervasive, and an employee believes that the general workplace milieu has become hostile and/or the ability to do his or her job has been compromised. Quid pro quo can be a single or a recurrent event(s) where an employee is pressured to engage in sexual behaviors due to job-related threats or benefits.

Social scientists define sexual harassment as any unwanted gender-based behavior that is offensive to the target, threatens the target's well-being, and/or overwhelms his or her coping abilities. Subtypes of sexual harassment have also been identified. *Gender harassment* includes a variety of sexist comments or behaviors that are often nonsexual in nature, such as asserting that all women are incompetent or unable to perform certain occupational duties. *Unwanted sexual attention* includes sexual comments, gestures, or physical contact, such as repeated requests for dates or attempts to kiss or touch the target. *Sexual coercion* is equivalent to the legal definition of quid pro quo and includes any job-related threats or benefits that are used to coerce sexual interaction, such as promises that an employee will be promoted or fired based on sexual compliance. Finally, *contrapower sexual harassment* involves any form of sexual harassment perpetrated by a subordinate and targeting a superior.

### Marginalized Populations

The majority of research on sexual harassment has been conducted with heterosexual, middle-class

White women, with little attention to diversity across these domains. Theorists assert that being both people of color and women places women of color at heightened risk for harassment (also known as double jeopardy). Research supports these theories, finding that compared to White women, women of color report being sexually harassed more often, experience harassment that is more severe and more sexualized (e.g., gender harassment versus unwanted sexual attention), and commonly describe racialized sexual harassment, where their sexual harassment is infused with race-based epithets or stereotypes. Similarly, studies document that lesbian women and economically vulnerable women are also subjected to more frequent and severe harassment than that reported in the general population. Women who are marginalized in multiple domains, such as lesbian women of color, are at even higher risk.

### Effects on Work, Health, and Psychological Well-Being

Sexual harassment is associated with a variety of negative consequences for targets. For example, compared to women who have not been sexually harassed, targets of harassment report increased absenteeism and job turnover and lower job satisfaction, work productivity, supervisor satisfaction, and organizational commitment.

Harassed men and women also demonstrate negative changes in almost every domain of physical health, including altered appetite, difficulty sleeping, increased headaches, gastrointestinal distress, and reproductive health concerns. Psychologically, they also report increased depression, anxiety, posttraumatic stress, and disordered eating symptoms. Similar to reactions to other forms of trauma, a subset of harassed employees engage in pathological coping such as increased binge eating and alcohol and drug use, all of which can exacerbate the consequences of other mental health concerns. Further, the negative effects of harassment in each of these domains may persist for years after the harassment itself has ended.

### Individual, Sociocultural, and Organizational Causes

Sexual harassment is the result of a variety of individual, social, and organizational factors. There is considerable variability across men with some being

more likely to sexually harass than others. Those who sexually harass others, compared to men who do not engage in harassment, frequently score lower on measures of empathy and higher on measures of sex-role stereotyping and rape myth acceptance. However, it is important to note that the development of these traits is not independent from sociocultural factors. In societies where women are devalued, sex-role stereotypes proliferate, gender-roles are imbalanced, and definitions of femininity and masculinity are separate and rigidly held, men are more likely to endorse sex-role stereotypes and rape myths. Concomitantly, the likelihood that sexual harassment will occur increases.

Organizations also differ in the likelihood that their employees will participate in sexual harassment, regardless of their individual predilections. Specifically, the job–gender context of a work group and the organization’s climate are powerful predictors of whether or not sexual harassment will occur. The job–gender context is determined by the ratio of men to women in a work group and by the extent to which the job is traditionally classified as a male or female occupation. Organizational climate refers to the general milieu within a workplace. Women in organizations that are tolerant of sexual harassment (e.g., demeaning attitudes toward women are modeled by superiors, harassers are not reprimanded) report much higher rates of sexual harassment than women in organizations that denounce gender inequities and sexual harassment in particular.

### How Organizations Can Stop Sexual Harassment

Independent of the expenses related to litigation, sexual harassment costs organizations millions of dollars every year due to factors such as increased absenteeism, job turnover, and reduced productivity. In response, organizations have initiated several strategies to reduce sexual harassment and limit their legal liability. Having a strong antiharassment policy, requiring sexual harassment training, investigating sexual harassment complaints quickly and efficiently, and enforcing penalties when harassment does occur can limit employers’ legal risk by demonstrating that they have exercised reasonable care to prevent, investigate, and remedy sexual harassment. These practices have been shown to reduce harassment within an organization, reduce negative outcomes for harassed

employees, decrease the likelihood of an employee initiating litigation, and reduce the organization’s legal liability.

## SEXUAL ORIENTATION

---

Sexual orientation describes a person's sexual or affectional attraction to another person specifically identified by gender, either opposite sex (heterosexually oriented), same sex (homosexually oriented), or both sexes (bisexually oriented). This entry focuses on sexual orientation as applied to a same-sex orientation or a bisexual orientation.

### Sexual Orientation and Career Counseling

Only 30 years ago there was little research addressing career counseling with lesbian and gay clients other than literature addressing such clients generally as “deviants.” That is now changing, and for career counseling professionals seeking practical advice on how to provide such counseling services, there is now a growing body of literature.

First, counselors who have lesbian, gay, and bisexual clients must become aware of the client's culture in order to be knowledgeable facilitators of growth and development—aware of the sociopolitical issues, specific knowledge, necessary information, and institutional barriers that confront gay and lesbian clients who seek career counseling, and also aware of the history, language, rituals, traditions, and sense of community that define the gay and lesbian culture. Finally, counselors must take a personal inventory of the ways that their often subtle or unconscious biases may influence the career counseling process.

Discrimination issues permeate all approaches to career counseling with sexual minorities because such discrimination colors the social and personal lives of all sexual, racial, and ethnic minorities. The special needs of this cultural minority arise from the historic discrimination that has helped define the gay and lesbian community and includes lack of civil rights; secret or semisecret lives; oppression,

rejection, or ostracism by family of origin; societal censure; lowered self-esteem due to internalized homophobia; fear and reality of physical violence; and campaigns of hatred and vilification by right-wing political groups and fundamentalist religious groups.

Career counseling with gay or lesbian individuals requires cultural counseling competence. Three seminal documents inform such competence: the Multicultural Counseling Competencies (American Counseling Association and Association for Multicultural Counseling and Development); the Association for Gay, Lesbian, and Bisexual Issues in Counseling Competencies for Counseling Gay, Lesbian, Bisexual and Transgender Clients; and the American Psychological Association's Guidelines for Psychotherapy with Lesbian, Gay, and Bisexual Clients.

Living in communities that routinely discriminate against gay men and lesbian women makes it virtually impossible for counselors to avoid internalizing negative stereotypes or attitudes about this sexual minority culture. Such misunderstanding will quickly be evident to sexual minority clients and may cause them to seek help elsewhere or not to get help at all. Counselors, however, must be familiar with gay and lesbian culture so that they are credible and congruent in their attitudes. Attending workshops, reading the literature, participating in lesbian and gay culture, and talking with former lesbian or gay clients or friends are effective ways to acquire knowledge about gay men and lesbian women and their culture.

Counselors need explicit awareness of their own religious and spiritual nature and beliefs. Counselors never impose their own belief system on their clients, but many lesbian and gay clients have been hurt by religious organizations.

Finally, counselors must confront their own individual prejudice and bias toward lesbian and gay clients and culture. The ethics codes of all the major mental health professional associations offer guidance for individuals who work with clients around issues related to their sexual orientation.

### Coming Out

A central issue for gay, lesbian, and bisexual persons' career development is coming out, the process of identifying as gay, lesbian, or bisexual and recognizing themselves as part of a stigmatized and semi-hidden minority. This identity development is a long

process usually beginning during adolescence, though sometimes considerably later.

There are two different types of coming out. On the one hand, coming out has been discussed as a developmental task for gay and lesbian individuals to successfully complete. This coming out involves a self-acceptance of the individual's own sexual orientation and might be better termed *coming out to self*. On the other hand, coming out has also been discussed as disclosing to others. Such disclosure might be accomplished by verbal or written, private or public statements to other individuals. By this action, individuals inform other persons of their sexual orientation. This might be better termed *coming out to others*.

The traditional stages of coming out to self include initial awareness of attraction to and feelings for the same sex; then experiences of sex; followed by explorations of the gay and lesbian cultural community; then self-labeling as lesbian, gay, or bisexual; and finally the disclosure of one's identity to others (coming out to others). Identity foreclosure, whereby the person stops his or her coming out process, can occur at any stage, or the individual can progress to the last stage with a fully integrated lesbian or gay cultural identity.

As part of effective career counseling, counselors need to address the "how to's" and the "why's" associated with deciding to come out to others, including considering the advantages and disadvantages of coming out in the workplace or school, providing opportunities for behavioral rehearsals to develop strategies for coming out to others, offering special services to meet the career development needs of lesbians and gays such as resume writing workshops (directly addressing issues of how far "out" to be on the resume or how many times the word *lesbian* is mentioned on a resume page, e.g., research on lesbian issues, teaching lesbian topics), and job interviewing workshops (training clients in responding to informational interview and job interview questions like "Are you married?" and "How many children do you have?").

### Job Discrimination

Discrimination against individuals on the basis of their race, ethnic origin, gender, disability, religion, political affiliation, or sexual orientation is a fact of life in U.S. society. Career counselors should recognize this and assist their clients in coping with this reality. In spite of increased visibility and acceptance, gay men and lesbian women continue to experience

discrimination in various aspects of their lives: in the workplace, when buying homes, when trying to adopt a child, and when seeking a marriage license to solemnize their relationships. Issues of dual and multiple discrimination also must be addressed when providing career counseling services. For example, lesbian women may face at least two forms of discrimination—sexism and heterosexism. If they are also a member of an ethnic or racial minority, older, or physically challenged, they may face daunting barriers to achieving their career goals.

For both lesbian women and gay men, discrimination based on sexual orientation is consistently listed among the top three most anticipated career-related barriers and is also expected to provide a moderately high degree of hindrance if encountered. Openly addressing such issues and preparing clients to cope with the more overt manifestations of racism, sexism, heterosexism, ableism, and ageism is an important role of the career counselor. Such discussions lead to improved decision making.

### Other Issues

Other issues that can be addressed in career counseling with gay, lesbian, or bisexual individuals include dual career same-sex couples, career counseling with racial and ethnic minority lesbians and gays, special assessment issues when using psychological inventories, use of gay and lesbian professionals as role models (informational interviews, job shadowing, internships, mentoring, etc.), special workplace services (mentoring programs, diversity workshops, and gay, lesbian, and bisexual affirmative policies such as nondiscrimination policies and domestic partners benefits), preparing special information for distribution to lesbian, gay, and bisexual clients (the geographic location and the size of the gay and lesbian communities in their area, the employment policies and Equal Employment Opportunity statements of local businesses, local and federal antidiscrimination laws), and even social advocacy for such clients (working to change employer-related statements or policies that discriminate, working toward changing the laws that criminalize certain sexual acts between two consenting adults, changing housing laws that do not allow two unrelated persons to live together, or working to stop police entrapment and unequal enforcement of laws).

## SOCIAL CLASS

---

Social class is implicated in almost every facet of the human experience, but for counselors and other mental health care providers, social class is difficult to understand. A lack of theoretical clarity between social class and socioeconomic status, not connecting classism as a function of social class, and psychologists' use of a sociological framework to understand a psychological experience has contributed to this problem. While sociologists typically study macrolevel experiences and tend to use income, education, and occupation to group individuals into discrete social class categories such as upper, middle, and lower class, psychologists are interested in the intrapsychic and interpersonal function and understanding of

social class and classism. Classifying people based on three criteria and then assuming people within that category see the world similarly may prove to be insufficient.

Instead, counselors should examine social class as a descriptor of another psychological construct or experience. For instance, counselors do not study race specifically, but explore racial identity and acculturation. In the case of social class, counselors could examine worldview and identity. Some researchers have embraced a social class worldview approach and advocated for classism to be considered a coconstruct to social class. Much like the study of race, racism is integral to the construction and maintenance of race. For social class, classism is related to the prejudice and discriminatory behaviors that perpetuate social inequalities and economic injustice. That is, societal inequalities are a result of classism in the sociopolitical (e.g., the unequal distribution of power), sociohistorical (e.g., biased and inaccurate histories of peoples), and sociostructural (e.g., legal, education, and economic systems) systems.

For counselors, it is suggested to explore the client's worldview associated with various aspects of social class and classism. First, it would be important to find a common language and understanding between client and counselor for social class that is rooted in theory and to allow for some clarity in the dyad. Second, counselors could explore how clients experience and understand how economic expectations potentially influence their behavior and attitudes. In session, they may explore how clients changed behaviors to fit in with new peer groups or how they negotiate materialistic needs. Third, counselors may examine how clients' classism experiences, either as the subject or perpetrator, have affected their sense of self and relationships with others. Finally, the session may focus on action related to changing attitudes and behaviors related to social class and classism. Future researchers should focus on developing psychologically based measures of social class and develop theory to link social class and classism. Working toward a phenomenologically based understanding of social class would help counselors integrate this cultural construct into their practice.

## SOCIAL COGNITIVE CAREER THEORY

---

Social cognitive career theory (SCCT) seeks to explain three interrelated aspects of career development: (1) how basic academic and career interests develop, (2) how educational and career choices are made, and (3) how academic and career success is obtained. Developed by Robert W. Lent, Steven D. Brown, and Gail Hackett in 1994, SCCT incorporates a variety of concepts (e.g., interests, abilities, values, environmental factors) from earlier career development theories, employing Albert Bandura's general social cognitive theory as a unifying framework.

Three intricately linked variables—self-efficacy beliefs, outcome expectations, and goals—serve as the basic building blocks of SCCT. *Self-efficacy* refers to an individual's personal beliefs about his or her capabilities to perform particular behaviors or courses of action. Unlike global confidence or self-esteem, self-efficacy beliefs are relatively dynamic (i.e., changeable) and are specific to particular activity domains. For example, people vary in their self-efficacy regarding the behaviors required in different occupational fields. One person might feel very confident of being able to accomplish tasks for successful entry into and performance in scientific fields, but feel much less confident about his or her abilities in social or enterprising fields, such as sales.

*Outcome expectations* refer to beliefs about the consequences or outcomes of performing particular behaviors (e.g., what will happen if I do this?). The choices that people make about the activities in which they will engage, and their effort and persistence at these activities, entail consideration of outcome as well as self-efficacy beliefs. For example, people are more likely to choose to engage in an activity to the extent that they see their involvement as leading to valued, positive outcomes (e.g., social and self-approval, tangible rewards, attractive work conditions).

*Personal goals* may be defined as one's intentions to engage in a particular activity (e.g., to pursue a given academic major) or to attain a certain level of performance (e.g., to receive an A in a particular course). By setting goals, people help organize and guide their own behavior and sustain it in the absence of more immediate positive feedback and despite inevitable setbacks. Social cognitive theory posits that goals are importantly tied to both self-efficacy and outcome expectations: People tend to set goals that are consistent with their views of their personal capabilities and of the outcomes they expect to attain from pursuing a particular course of action. Success or failure in reaching personal goals, in turn, becomes important information that helps alter or confirm self-efficacy beliefs and outcome expectations.

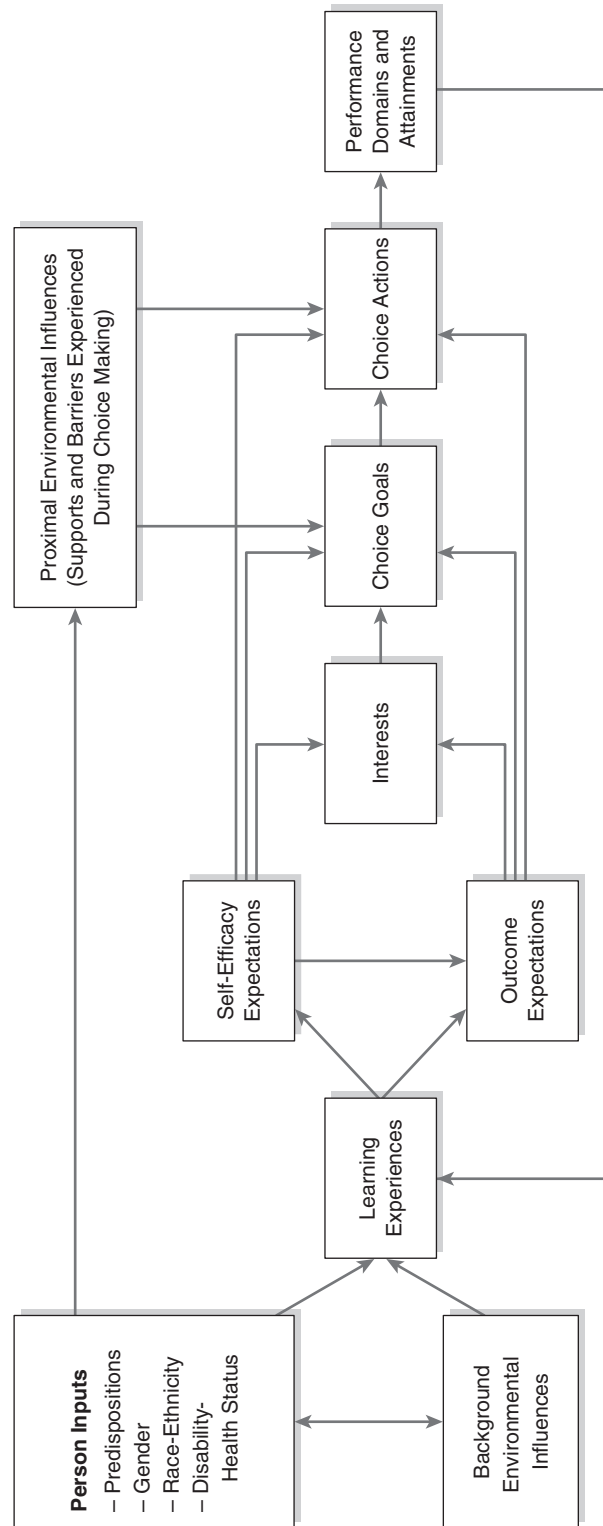

### Interest Model

As shown in Figure 1 (center), interests in career-relevant activities are seen as the outgrowth of self-efficacy and outcome expectations. Over the course of childhood and adolescence, people are exposed, directly and vicariously, to a variety of occupationally relevant activities in school, at home, and in their communities. They are also differentially reinforced for continuing their engagement, and for developing their skills, in different activity domains. The types and variety of activities to which children and adolescents are exposed are partly a function of the context and culture in which they grow up.

Through continued activity exposure, practice, and feedback, people refine their skills, develop personal performance standards, form a sense of their efficacy in particular tasks, and acquire certain expectations about the outcomes of activity engagement. People are most likely to develop interest in activities at which they both feel efficacious and expect positive outcomes. As people develop interest in an activity, they are likely to develop goals for sustaining or increasing their involvement in it. Further activity involvement leads to subsequent mastery or failure experiences that in turn help revise self-efficacy, outcome expectations, and ultimately interests within an ongoing feedback loop.

In sum, people are likely to form enduring interest in an activity when they view themselves as competent at performing it and when they expect the activity to produce valued outcomes. Conversely, interests are unlikely to develop in activities for which people doubt their competence and expect negative outcomes.

**Figure 1** A simplified view of how career-related interests and choices develop over time, according to social cognitive career theory

Source: Adapted from R. W. Lent, S. D. Brown, and G. Hackett (1994).

Furthermore, SCCT posits that for interests to blossom in areas for which people have talent, their environments must expose them to the types of direct, vicarious, and persuasive experiences that can give rise to robust efficacy beliefs and positive outcome expectations.

### Choice Model

SCCT's model of the career choice process, which builds on the interests model, is also embedded in Figure 1. Arising largely through self-efficacy and outcome expectations, career-related interests foster particular educational and occupational choice goals (e.g., intentions to pursue a particular career path). Especially to the extent that they are clear, specific, strongly held, stated publicly, and supported by significant others, choice goals make it more likely that people will take actions to achieve their goals (e.g., seek to gain entry into a particular academic major, training program, or job). Their subsequent performance attainments (e.g., successes, failures) provide valuable feedback that can strengthen or weaken self-efficacy and outcome expectations and ultimately help to revise or confirm choices.

As illustrated in Figure 1, SCCT also emphasizes that choice goals are sometimes influenced more directly and potently by self-efficacy beliefs, outcome expectations, or environmental variables than they are by interests. Interests are expected to exert their greatest impact on academic and occupational choice under supportive environmental conditions, which enable people to pursue their interests. However, many adolescents and adults are not able to follow their interests either unfettered by obstacles or with the full support of important others. The choice making of these persons is constrained by such experiences as economic need, family pressures, or educational limitations. In such instances, people may need to compromise their interests and instead make their choices on the basis of such pragmatic considerations as the type of work that is available to them, their self-efficacy beliefs ("Can I do this type of work?"), and outcome expectations ("Will the job pay enough to make it worthwhile?"). Cultural values (e.g., the degree to which one's choices may be guided by elder family members) may also limit the role of personal interests in career choice.

SCCT posits conditions that increase the probability that people will be able to pursue their interests as

well as conditions where interests may need to be compromised in making career-related choices. Collectively labeled environmental influences in Figure 1, these conditions refer to the levels of support (e.g., family financial and emotional support), barriers (e.g., lack of finances, inadequate levels of education), and opportunities available to the individual. Simply put, SCCT hypothesizes that interests will be a more potent predictor of the types of choices people make under supportive rather than under more restrictive environmental conditions. Under the latter conditions, one's interests may need to be bypassed or compromised in favor of more pragmatic, pressing, or culturally acceptable considerations.

### Performance Model

SCCT's performance model is concerned with predicting and explaining two primary aspects of performance: the level of success that people attain in educational and occupational pursuits and the degree to which they persist in the face of obstacles. SCCT focuses on the influences of ability, self-efficacy, outcome expectations, and performance goals on success and persistence. Ability (as reflected by past achievement and aptitudes) is assumed to affect performance via two primary pathways. First, ability influences performance and persistence directly. For example, students with higher aptitude in a particular subject tend to do better and persist longer in that subject than do students with lesser aptitude. Second, ability is hypothesized to influence performance and persistence indirectly through the intervening paths of self-efficacy and outcome expectations.

In other words, performance involves both ability and motivation. SCCT emphasizes the motivational roles of self-efficacy, outcome expectations, and performance goals. Specifically, SCCT suggests that self-efficacy and outcome expectations work in concert with ability, in part by influencing the types of performance goals that people set for themselves. Controlling for level of ability, students and workers with higher self-efficacy and more positive outcome expectations will be more likely to establish higher performance goals for themselves (i.e., aim for more challenging attainments), to organize their skills more effectively, and to persist longer in the face of setbacks. As a result, they may achieve higher levels of success than those with lower self-efficacy and less positive outcome expectations. Thus, favorable

self-efficacy, outcome expectations, and goals help people to make the best possible use of their ability.

## Research and Practical Applications

A substantial body of research has accumulated suggesting that SCCT is a useful framework for explaining various aspects of educational and vocational interest development, choice making, and performance. The theory has also recently been extended to the understanding of academic and work satisfaction. SCCT has sparked a number of efforts to design and test interventions aimed at various facets of career development. It has also been applied to the study of career behavior in a number of countries and cultural contexts.

## SOCIAL DISCRIMINATION

Discrimination is a complex social problem that affects individuals, groups, organizations, and society as a whole. Scholars describe discrimination as consisting of types (e.g., subtle or overt), occurring across levels (e.g., individual, institutional, cultural), and in relation to its targets (e.g., racial or ethnic, sexual, sexual orientation). The focus of study in many disciplines and a common element across definitions is that discrimination is an unfair action or behavior that results in negative outcomes for targeted social groups or their members.

Discrimination can be experienced as a major event or as a chronic condition, such as an ongoing barrier to resources. The cause of discrimination is the subject of much social science research and has been conceptualized in various ways, but is typically linked to prejudice and stereotyping, which are thought of as the attitudinal and cognitive components, respectively, that underlie discrimination. A widespread phenomenon, discrimination can be observed by asking individual targets for their perceptions of discriminatory experiences or through its impact on targeted groups. Proposed remedies for discrimination are numerous and may vary by target group.

## Historical Perspective

The United States has a lengthy, discreditable history of legally sanctioned discrimination toward targeted social groups. A few examples are the forced relocation of Native American peoples, enslavement of African Americans, denial of voting and reproductive rights to women, the Chinese Exclusion Act of 1882, internment of Japanese Americans during World War II, and the criminalizing of same-sex sexual behavior. Although legal protections have been extended to some oppressed groups (e.g., Civil Rights Act of 1964, Age Discrimination in Employment Act of 1967, Americans with Disabilities Act of 1990), discrimination is far from being eliminated as a social problem. Target groups continue to experience economic, political, and social disadvantages.

A few examples from the work world include significantly lower rates of pay for Hispanics, Native Americans, and African Americans compared to Whites; substantially higher rates of unemployment for people with disabling conditions compared to

those without; more frequent and severe sexual harassment for women when compared to men; and the lack of legal protections on the basis of sexual orientation for lesbians and gay men (e.g., organizational policies and practices can explicitly deny employment on the basis of sexual orientation).

### Levels and Types

Discrimination at a structural or institutional level, also called differential effect, appears to be neutral, but has the effect of disadvantaging target groups or advantaging majority groups. It can operate in social or organizational policies and practices that result in an adverse impact on target groups. Currently, legal protections in the workplace are provided on the basis of an employee's race, color, national origin, sex, religion, age, and disability status. However, prior to such protections, targeted groups (e.g., women, minorities, immigrants) could be hired, fired, and treated differently on the job on the basis of group characteristics such as sex, race, national origin, or religion. This history of legally sanctioned discrimination had the effect of segregating target groups into low-paying, low-prestige jobs with few opportunities for advancement. Although former practices such as advertising women's and men's jobs are legally prohibited, current practices such as word-of-mouth advertising can have the effect of getting the word out to those who are in one's social category, thus excluding others.

Cultural discrimination also operates at the macro level and refers to privileging a particular social group's cultural values. Examples can be seen in media representations that negatively skew a target group's values and cultural expressions or that present culture only from a majority viewpoint.

At an individual level, discrimination is behavior that benefits a majority group or group member or disadvantages a target group or group member. Such behavior, also referred to as differential treatment, is often typed as overt or subtle. Overt discrimination is intentional and explicit and has become less acceptable today than it was prior to the passage of Civil Rights legislation. However, this old-fashioned type continues to exist and includes a range of behaviors such as denial of employment to a person with a disability, hostile verbal harassment directed to an ethnic minority person, or physically assaulting a gay man. Associated with beliefs in the superiority of one's own social group, overt discrimination is behavior aimed

at maintaining power over a social group or individual from a group that is regarded as inferior.

Subtle discrimination, the more common type, is covert and is often unintentional behavior that can operate at an unconscious level. An example is a male manager who regularly invites his male colleagues and subordinates to golf outings after work because he feels he has a lot in common with them, an activity that creates opportunities for the male subordinates, but not for the female, to engage in informal networking, thus gaining access to work and advancement information and to potential mentors.

There is a rich literature about the complex causes of discrimination. One commonly cited view suggests that discriminatory behavior stems from biased attitudes, judgments, and feelings about a social group or an individual based on group membership. Subtle forms are thought to take place when majority members hold prejudices or ambivalent feelings about a target group, perhaps unconsciously, but may view themselves as nonprejudiced. Overt expressions of discrimination are socially unacceptable and run counter to self-image, thus biases are expressed subtly (e.g., nonverbal behavior, endorsing beliefs that appear neutral but that disadvantage a target group).

Harassment in the workplace, a subtype of discrimination, includes behaviors that create a hostile, offensive, or intimidating work environment that unreasonably interferes with an individual's work performance. Sexual harassment also includes behaviors that coerce sexual cooperation by threat of job detriment or promises of advancement. The antecedents of sexual harassment in the workplace that have received the most empirical support are an organizational climate that is tolerant of such behavior and a skewed gender context (i.e., gender of immediate supervisor, gender ratio of the workgroup, and gender typing of the occupation).

### Targets, Extent, and Consequences

Discrimination is often described in terms of its target groups. Although all targeted groups experience discrimination, there is variability within groups in individual members' perceptions of discrimination and the degree to which they experience harm. There are also between group differences that can affect how experiences of discrimination are conceptualized in each group. Groups differ in the degree to which they are visible to others. For example, sexual minorities and people with certain disabling conditions may not be identifiable unless they choose to disclose. Civil rights

protections have been extended on the basis of some target characteristics (e.g., race, color, national origin, sex, religion, age, and disability status) but not others (e.g., sexual orientation, stigmatizing conditions). Groups also have unique histories with discrimination (e.g., slavery, Holocaust) that can influence current experiences of personal or institutionalized discrimination. Historical experiences can also influence behavior or group identity over successive generations. Discrimination takes place within arenas or domains such as labor markets (e.g., job segregation, glass ceiling), education (e.g., graduation rates, placement in special education), housing and lending markets (e.g., access to home loans), criminal justice (e.g., arrest rates, sentencing, policing), and health care (e.g., access, quality). There are differences in how target groups fare with respect to access and function in each domain. The two groups most often studied are African Americans and women, and research about these two groups has influenced research on other groups. One consideration in the literature is whether there is a general model, applicable across groups, to explain discrimination and its resulting harm or whether the factors associated with discrimination are group specific.

It is difficult to determine the presence or extent of discrimination because it is typically observed indirectly, for example, through individual perceptions of discrimination or by an inferential process such as examining differential outcomes (e.g., lower rates of pay) for a target group. Estimates of perceived discrimination depend on the time frame (e.g., 12 months, lifetime), the questions that are asked (e.g., "Have you experienced sexual harassment?" vs. "Have you experienced unwanted sexual advances?"), and the context for the behaviors (e.g., work, housing, medical care). Lifetime prevalence estimates for African Americans that examine discrimination across contexts suggest that 98% have experienced discrimination. Research about work-related discrimination suggests 60% of African Americans experience work-related discrimination. Sexual harassment is estimated as affecting 50% of women employees. Between 25% and 66% of lesbian and gay male employees are thought to experience discrimination or harassment based on sexual orientation in the workplace (e.g., derogatory jokes, termination of employment). Sometimes referring to it as double jeopardy, research finds that the frequency of discrimination is greater if an individual is a member of

multiple target groups. For example, minority women are more likely to experience harassment in the workplace than are minority men, White men, or White women. Minority women, compared to White women and minority men, are segregated into lower-paying and lower-prestige jobs.

Field research has been useful in determining whether discrimination takes place in particular contexts, such as the housing market or in hiring. Administrative records can provide evidence of whether complaints of discrimination have been made in a particular setting. Social scientists use statistical analysis of nationally representative datasets or data from a particular organization to determine whether target groups are experiencing adverse impact (e.g., occupational segregation for Hispanic workers). Survey research is used to examine perceived experiences of discrimination. Each of these methods has made contributions to understanding various aspects of discrimination, but no one method provides a complete picture of the extent of discrimination. Ultimately, the best approach is one that uses multiple methods.

## Consequences

A large body of research links discrimination and harassment to decreased psychological and physical well-being and decrements in work-related attitudes for target groups. A number of theoretical models attempt to explain the factors associated with the harm process. A common element across various models is that discrimination acts like a stressor that, when appraised as exceeding the target's ability to cope (stressful or threatening), leads to decreased well-being. Targets employ various coping responses (e.g., assertion, cognitive, or behavioral avoidance) in an attempt to manage the discrimination. Variations of this cognitive appraisal process have been incorporated into theoretical formulations describing how discrimination harms women, African Americans, Asian Americans, and sexual minorities.

Researchers have identified numerous other harm-enhancing or harm-buffering factors that relate to the target of the discrimination (e.g., hardiness; vulnerability; active and passive coping responses; attributions about the behavior, perpetrator, one's self, and one's social group; pride in and identification with one's social group), the behavior itself (e.g., frequent and severe experiences, experiences across types or domains, perpetrator characteristics), or the context in

which it takes place (e.g., how the organization or institution responds to the discriminatory behavior, the target, and the perpetrator). Despite the volume of research in this area, factors associated with discrimination have received differing degrees of empirical support and may be more or less relevant depending on the target group. Thus, it is challenging to point to one set of factors that work in the same manner across groups.

### ***Racial and Ethnic Discrimination***

Perceived racial discrimination in African Americans is associated with increased psychiatric symptoms and psychological distress, lower life satisfaction, negative health behaviors (e.g., cigarette smoking), and decreased physical health (e.g., hypertension). It also influences job-related outcomes for racial and ethnic minorities, such as decreasing satisfaction while on the job. Although the vast majority of studies on racial or ethnic discrimination have focused on African Americans, empirical research makes it obvious that Asian Americans, Hispanics, Native Americans, Arab Americans, and other racial and ethnic target groups experience discrimination and that it affects their psychological and physical health as well as their job attitudes. Additionally, discrimination has been linked to higher morbidity and mortality rates for African Americans, American Indians, and Hispanics compared to White Americans.

### ***Sexual Discrimination***

The majority of outcome research on gender-based discrimination has focused on the consequences of sexual harassment, a form of sexual discrimination. A large body of research links sexual harassment to negative and costly outcomes for both individuals and organizations. It is associated with psychological and health outcomes such as alcohol abuse, increased risk of eating disorders, health problems, distress, posttraumatic stress disorder, and symptoms of other mood and anxiety disorders. Job-related consequences, such as decreased job satisfaction and organizational commitment, increased job and work withdrawal, and job turnover, are also well documented. Although much of the research focuses on harmful consequences to targets, sexual harassment is also damaging to employers. Job turnover and the subsequent need to recruit, hire, and train new personnel are costly to organizations as are increased usage of health care and employee absences.

### ***Discrimination Based on Sexual Orientation***

Disclosure of sexual identity is linked to workplace harassment and discrimination, with some scholars hypothesizing a direct link between disclosure and ensuing experiences of harassment and discrimination while others suggest that perceptions of discrimination drive whether one conceals or discloses. However, research is clear that the discrimination itself is associated with harm to physical and mental health, including increased alcohol and drug usage, psychological symptoms, distress, and perceptions of poor health. Likewise, hate crime victimization outside of the workplace is associated with decreased physical and psychological well-being.

### ***Remedies***

Reducing discrimination is beneficial for target groups and organizations. It reduces costs attributable to discrimination, such as turnover, absenteeism, and legal costs associated with claims of discrimination. It also creates a more diverse workforce, a result that according to research has potential to benefit organizations. Research about harassment suggests that the attitudes and behaviors of organizational leaders and top management influence the degree to which harassment is tolerated in an organization. Unbiased attitudes of top management and organizational action in response to harassing behavior can reduce the overall amount of harassment in an organization. Factors thought to reduce harassment and discrimination include bringing target group members to numerical parity with majority group members within work groups, rewarding intergroup cooperation, and creating an organizational climate that supports diversity and does not allow for discrimination. Organizations can also review and eliminate policies and procedures that lead to having an adverse impact on target groups and can institute strong policy statements prohibiting discrimination. They can also provide diversity training and resources for targets of discrimination.

## SOCIETY FOR VOCATIONAL PSYCHOLOGY

---

The Society for Vocational Psychology is a professional organization that has as its purpose to encourage, promote, and facilitate contributions to research, teaching, practice, and public interest in vocational psychology and career intervention. The society is one of several interest groups within the Society of Counseling Psychology (Division 17) of the American Psychological Association. Society membership includes psychology graduate students, faculty, researchers, consultants, and practitioners.

The society promotes its goals by sponsoring presentations at the annual meeting of the American Psychological Association, by publishing and distributing information relevant to its members via a Web site and an electronic newsletter, by representing the interests of career development and vocational psychology within the Society of Counseling Psychology and the American Psychological Association, and by sponsoring and cosponsoring national and international conferences.

The Society's Biennial Conference Series has sponsored eight conferences since its inception in 1992. Conference themes have addressed diverse issues from prospects for convergence in career theory and practice, to advances in interest measurement, to reflections on the construct of self in career psychology. Two of the society's biennial conferences have been international conferences (Coimbra, Portugal, and Vancouver, British Columbia, Canada), and several of the conference

themes were captured in print (Savickas & Lent, *Convergence in Career Development Theories: Implications for Science and Practice*, 1994; Savickas & Spokane, *Vocational Interests: Meaning, Measurement, and Counseling Use*, 1999). The society also advances its goals by working closely with related organizations such as the National Career Development Association, the International Association for Educational and Vocational Guidance, and the American School Counselor Association.

The society traces its origins to a Special Interest Group (SIG) within the Society of Counseling Psychology. Founded in 1987 by Mark Savickas (Northeastern Ohio Universities College of Medicine), the SIG quickly grew in size. In 1994, a committee chaired by Linda Subich (University of Akron) and consisting of Nadya Fouad (University of Wisconsin–Milwaukee), Thomas Krieshok (University of Kansas), Ellen Lent (George Washington University), Robert Lent (University of Maryland), Scott Solberg (University of Wisconsin–Milwaukee), Jane Swanson (Southern Illinois University), Tony Tinsley (Southern Illinois University), Don Zytowski (Ames, Iowa), and Bruce Walsh (Ohio State University) petitioned the Society of Counseling Psychology for status as a section. The society gained section status in August 1996.

Today the society enjoys a student and professional membership of over 400 individuals. The society has thrived under the leadership of past chairpersons (Linda Subich, Nadya Fouad, Jane Swanson, Bruce Walsh, David Blustein, and Paul Gore) and continues to advance research, practice, and theory in vocational psychology and career development through scholarship, education and training, and mentorship.

## SPIRITUALITY AND CAREER DEVELOPMENT

---

Career counseling is a dynamic process of helping clients explore how aspects of their identity may relate to their career decision making or ability to cope with work difficulties. Although researchers have examined how a wide range of personal and relational variables relate to career development, few studies have explored how spirituality, which can be a unique and often powerful component of an individual's life, may relate to the career development process. In fact, most major theories of career counseling do not address the role of spirituality explicitly, and counselors may be overlooking a variable that may be critical to many clients' career development. Thus, counselors are encouraged to simply ask their clients if they are spiritual and if so to explore how this component of their life may relate to their career process.

Based on research in the fields of vocational psychology and spirituality, it is proposed that a client's spirituality may interface with a client's career in at least three ways: as a means of support, as an influence on career-related interests and values, and as a motivator of career choice by way of a calling or vocation. However, it is likely that the uniqueness of a client's spirituality may be matched by the uniqueness in which it relates to his or her career. By addressing these connections, counselors may have a deeper understanding of a client's identity and also normalize the notion that spirituality may be important in career-related tasks. This entry discusses the various ways spirituality may be linked to career development and how counselors can use these relationships to provide more effective counseling.

## What Is Spirituality?

Prior to discussing the relationship between spirituality and career development, it is necessary to first understand what spirituality means. As research exploring spirituality has grown exponentially over the past 20 years, a number of definitions have emerged. Many scholars view spirituality as distinctly tied to religiousness and define spirituality as the relationship an individual has with a higher power or powers. In general, others define this term as a search for meaning in the pursuit of highest human potential. In this case, spirituality entails striving to attain or achieve a goal. Still other scholars consider spirituality a general life force that serves to guide one's decision making and ways of living. Although definitions vary, their commonality is that spirituality, unlike religiousness, tends to be considered unique, individualized, and adaptable. It is likely that no two individuals' spirituality would be exactly alike, that it may vary within and across cultures, that the degree it influences one's life would greatly vary, and that many more people would claim to be spiritual than religious. Recent large-scale studies have found that 40% of people report following religious teachings in everyday life, while 80% report an interest in spirituality and 83% believe in the sacredness of life. Research has shown that regardless of the precise definition, spirituality can have a large impact on one's life, including one's career.

## The Interface of Spirituality and Career Development

The study of spirituality in general has recently burgeoned, and in turn additional investigations have begun to explore how spirituality relates to careers and work. A series of theoretical models have been proposed that link spirituality and career development, and each model emphasizes that individuals' spirituality should be considered in their decision-making process as it may be a critical component of their self-concept. A minimal amount of empirical research has also been completed, addressing the connections between spirituality and specific career-related variables. For example, researchers have found that college students who had greater spiritual awareness or a strong spiritual presence in their lives reported higher career decision self-efficacy and career choice commitment. For working adults, indices of

spiritual well-being have been tied to greater job satisfaction. Other qualitative studies with college students and adults have found that spiritual individuals report a greater desire to serve others, that they feel more supported during career-related struggles, and that they are more likely to view their career as a calling. What this theoretical and empirical work suggests is that spirituality may be inexplicably linked to interest and value development, decision making, and coping in all stages of the career process. This notion may be especially important for career counselors who work with clients in helping them both make career decisions and cope with the world of work.

## Spirituality and Career Counseling

Recent reviews of the career counseling literature have found that career counselors are both retaining many of the older "three sessions and a cloud of dust" principles and also incorporating new techniques that bridge a client's career and relational life. Indeed, career counseling today is ideally a dynamic process through which counselors help clients explore not only their interests, skills, and values, but also their familial influence, work-family conflict, and supports and barriers. Without understanding the full scope of factors that may influence a client's career, including spirituality, counselors may be missing information that could be critical to helping clients make decisions and cope with the world of work. The following sections focus on how a client's spirituality and career may intertwine, with particular focus placed on spirituality as a form of support, as an influence on career interests and values, and as a choice motivator.

### *Support*

For college students in the process of making career decisions, and especially for working adults dealing with career-related stress, having a strong support network can be critical. Typically, counselors have been encouraged to investigate and draw on the support a client receives from friends, family, and significant others. Research has shown that individuals who feel more supported by these sources report higher levels of career decision self-efficacy, career exploration, perceptions of career and educational opportunities, and job satisfaction. These support networks typically provide safety nets to fall back on

during stressful times and are sources of advice and guidance. However, the support individuals may receive through their spirituality has received minimal attention from researchers, and no studies have examined how spiritual support relates to the career development process.

So how can spiritual support be explored in career counseling? First, it is recommended that counselors ask clients if they are spiritual and then encourage them to explain what spirituality means to them. As stated previously, spirituality will likely mean something unique to each individual client and can range from a relationship with a higher power or powers to a belief in a general life force. If a client is spiritual, counselors are encouraged to explore if and to what extent he or she derives support from his or her spirituality. For some clients, this support may come from connecting with a higher being, perhaps in the form of prayer or meditation. For others, support may come from connecting with other individuals in their spiritual community who may share similar beliefs and value systems. Regardless of the exact mechanism through which support is received, spiritual support can be powerful, especially for individuals who view their spirituality as a principal component of their self-concept. Without raising the question of the extent of a client's spirituality, counselors may be overlooking an important piece of the client's overall support network.

### ***Interests and Values***

Two of the most important constructs in the study of career development are interests and values. In nearly all major theories of career counseling, counselors are encouraged to explore with clients their specific career interests and values and, time permitting, discuss how these developed. Through extensive research, vocational psychologists have found that these constructs do not develop in a vacuum, but rather are influenced by a variety of factors including family, personality, gender, quality of education, self-efficacy, and even spirituality. In addition, more limited research suggests that individuals who consider themselves to be spiritual report a greater desire to serve others and are more likely to be found in social jobs.

When working with clients who are spiritual, it is suggested that counselors be aware of how this important component of their life relates to their values and

interests. If a client's spirituality serves as a guiding life force, then these principles will likely affect what he or she desires out of a job or career. For example, if a central component of a client's spiritual beliefs is to positively contribute to society or help others in some way, it would not be surprising if at an early age interests in social careers or altruistic work values developed. Many spiritual clients may have explicitly felt this influence, while for others it may be implicit, with their spiritual values so entrenched within their overall development it would be difficult to isolate them. In sum, it will be impossible to understand the full impact spirituality may have on a client's interest and value development if this possibility is not addressed.

### ***Career Choice***

For students in the process of exploring career options and adults interested in switching jobs or careers, making an informed choice is a critical final step. In fact, in most major theories of vocational development, choice implementation is the desired outcome variable. A variety of factors contribute to the ability to make an effective choice, including, but not limited to, exploration, self-efficacy, interests, values, skills, and support. For some clients, however, their unique spirituality may serve to influence their actual career choice by way of a *calling* or *vocation*. Each of these terms has been defined in a variety of ways. For example, calling has been defined as a summons by God to a certain career, a call to serve God, and as a quest for fulfillment in work and desire to impact society. Similarly, vocation has been described as an overwhelming desire to find meaning in one's life through work and as a call to something larger than oneself. What these terms have in common is the notion that individuals may make career decisions with less of a focus on personal factors such as skills, interests, or prestige and more of a focus on a career they feel pulled to by some external power or societal need.

Because of the scarcity of research on this topic, it is unclear what percentage of clients may feel they have a calling or vocation to a particular career or may be searching for one. It is also unclear the degree to which such a call may emanate from religious or spiritual factors or simply from a desire to serve others. Regardless, it is suggested that counselors explore with spiritual clients the extent to which they feel they

have a calling or vocation and in turn what these terms mean to them. For clients who feel they have a strong calling to a certain career, it is suggested that the counselor assess the degree to which this affects their ultimate career choice. Also, clients who are especially religious or spiritual may be searching for a calling or vocation, and counselors could be particularly instrumental in this process. For clients who are seeking out a calling or vocation, it is suggested that counselors encourage them to explore their own internal interests, abilities, and values, as these may dovetail with an eventual calling or vocation and can guide clients into the areas of work that may be most satisfying for them. Though the constructs of calling and vocation are complicated and perhaps not pertinent to all career clients, it is recommended that counselors be open to exploring these variables, especially with spiritual clients.

## STANDARDS AND COMPETENCIES

---

Standards and competencies in counseling represent attempts to articulate tacit knowledge into criteria and to regulate professional behavior. They are also important as the foundation of efforts in personnel certification and program accreditation. Standards are ubiquitous across modern society. Transnational bodies regulate standards through a representation process. The International Organization for Standardization (ISO) creates and manages standards development through technical committees and a six-step process for achieving consensus. The International Accreditation Forum then oversees implementation and conformity across the world through a system of conformity audits managed by disinterested third parties. The American National Standards Institute is the American representative to ISO. Standards, which govern many aspects of technology, exist for quality (ISO-9000 since 1987), for environmental management (ISO-14000 since 1996), and for personnel certification (ISO-17024 since 2003). The ISO/ANSI 17024 standard has implications because certification providers may wish to seek accreditation to document the quality of their programs. An inherent danger of standards and competencies is that they become checklists honored in letter rather than in spirit and replace innovation with adherence.

Nearly a decade ago, standards for career counseling were discussed using a three-C framework of colleagues, competencies, and credentials. Colleagues are often located within professional associations, whereas competencies specify clusters of personal attributes (knowledge, skills, abilities, and attitudes) related to effective performance of counseling duties and tasks. Credentials cover the traditional domains of government licensing and voluntary certification. Brooke Collison, writing in 2001, used a similar framework of professional associations, accreditation standards, and credentialing

Viewed from this perspective, standards and competencies are ways to develop agreements (and occasionally disagreements) about quality products, processes, programs, and personnel within the counseling profession. Standards are statements to which individuals and organizations can compare their actions, for example, in such key areas of professional performance as testing and assessment, ethics, and graduate education and training. Competencies are behavioral clusters reflecting application of knowledge and skill to achieve superior performance. The key assumption involved in creating and using standards and competencies that achieve quality in counseling products, processes, programs, and personnel will translate into improved counseling outcomes. Standards and competencies in counseling are developed by professional associations and groups, such as the American Counseling Association, the National Career Development Association, and the Council on Accreditation in Counseling and Related Educational Professions (CACREP). They are often the foundation of licensing and certification systems for individual counselors and accreditation systems for counselor education and training programs. The personnel credentialing function is fulfilled by the National Board for Certified Counselors together with its partner, the American Association for State Counseling Boards. The accreditation function is undertaken by CACREP.

Equally pivotal for the counseling profession are general standards in ethics and in testing. In ethics, the American Counseling Association issued its latest Ethical Code in 2005 as a set of eight standards. The American Psychological Association released its most recent set of standards in 2002. In testing, the *Standards for Educational and Psychological Testing* were developed jointly by the American Educational Research Association, American Psychological Association, and

the National Council on Measurement in Education and released in 1999 (and are currently under revision). There are 264 testing standards presented with respect to test construction, subgroup bias, and applications of testing. A typical competency system is one developed and validated for Microsoft (by Lominger International), then modified and released free-of-charge to the education sector in six categories of results, courage, organizational skills, individual excellence, operating skills, and strategic skills.

### **Multicultural Counseling Competencies**

In addition to traditional competencies in counselor education and training, a significant emerging set pertains to multicultural counseling competencies (MCC). Thirty-one competencies were developed in 1991 by the Association of Multicultural Counseling and Development and described by Derald Wing Sue, Patricia Arredondo, and Roderick J. McDavis in 1992. These authors and others have called the counseling discipline to action. A sample competency statement is built around culturally competent counselors “seeking to understand themselves as racial and cultural beings and actively seeking a nonracist identity” (Sue, Arredondo, & Roderick, p. 482). The competencies are statements defined in a matrix framework with three psychological dimensions—beliefs and attitudes, knowledge, and skills—crossed with three characteristics: (1) counselor awareness of own assumptions, values, and biases; (2) understanding the worldview of the multicultural client; and (3) developing appropriate intervention strategies and techniques. In 2002, the American Psychological Association adopted a statement titled “Guidelines on Multicultural Education, Training, Research, Practice, and Organizational Change for Psychologists,” which is available at the Web site of that association. Practice and research accomplishments in MCC over the last 15 years are summarized in the 2006 *Handbook of Multicultural Competencies in Counseling and Psychology* edited by Donald Pope-Davis and colleagues. The handbook includes over 30 chapters in six sections of concepts and theories, assessment, research, practice, and teaching. Various authors provide descriptions and evaluations of scales developed to measure MCC, but the research support is not as robust as desired, or as indicated as in the concluding chapter by Donald

Atkinson and Tania Israel. A 2006 meta-analysis reported by Timothy Smith, Madonna Constantine, Todd Dunn, Jared Dinehart, and Jared Montoya, however, shows a consistent effect for multicultural education and a larger effect for theory-based programs.

### Developing Standards and Competencies

Finally, whenever standards and competencies are evaluated worldwide, the processes of creation and revision should be scrutinized. Among the important desiderata of quality are engaged stakeholders, a planned and iterative process, public comments, and an approval process involving the professional membership. Revision process and cycles should be considered as well. For example, the American Psychological Association in the mid-1990s revised the accreditation process and principles to counter critiques of a checklist mentality that had arisen. One response to those revisions was a normative or prescriptive training program in counseling psychology such as the one outlined in 1998 by Nancy Murdock and her colleagues.

A summary of the important sets of standards and competencies for the counseling profession is shown in Table 1.

## STRONG, EDWARD KELLOGG, JR. (1884–1963)

---

Edward Kellogg Strong, Jr., born in 1884 in Syracuse, New York, was the first author of the Strong Interest Inventory (Strong). At the age of 40, Strong took a position in the School of Business at Stanford University where he began his research in interest measurement. He remained at Stanford until his retirement in 1949. After his retirement, Strong continued his work in interest measurement in collaboration with his son-in-law, Ralph F. Berdie, who was a professor at the University of Minnesota, and with other Minnesota faculty including Donald G. Paterson, John G. Darley, David P. Campbell, Theda Hagenah, Wilbur L. Layton, Edmund G. Williamson, and Kenneth E. Clark. After Strong's death in 1963, the University of Minnesota established the Center for Interest Measurement Research, now directed by Jo-Ida C. Hansen, and all of Strong's data were moved from Stanford to Minnesota. The most recent revision of the Strong was published in 2004, making it the longest continuously published interest inventory. The longevity of the Strong, which still uses Strong's method of empirical contrast groups to construct occupational scales, is due in large part to the early work of Strong who laid the empirical foundation for the inventory.

### Before Interest Measurement

Strong lived in many parts of the United States during his lifetime. His father was a minister, and when Strong was a child they moved to the Midwest (Bloomington, Illinois, and Bay City, Michigan) where he developed a love for the outdoors. In 1902, the family moved to San Francisco, and Strong attended the University of California, Berkeley where he majored in biology. After college, Strong spent a year with the U.S. Forestry Service. His love for the Sierras and the outdoors was a constant throughout his life, and at the time of his retirement his score on the Strong Nature scale was one of the three highest scores on his profile (the other two were Science and Mathematics). Strong's daughter described his love for nature in a 1987 interview: "He loved his garden and his golf. He especially loved the mountains, the ocean and the desert. He knew the names of the plants and trees and was continually teaching them to us. He also knew the constellations of stars. He loved to be in the outdoors—to hike, to swim, or to fish" (Hansen, 1987, p. 121).

Strong returned to Berkeley and completed an M.A. in psychology in 1909. He then moved back to the East to attend Columbia University. As a graduate assistant working with Harry L. Hollingworth at Bernard College, Strong met an undergraduate, Margaret Hart, whom he married in 1911, the same year that he completed his Ph.D. Strong remained at Columbia until 1914 when he joined the psychology faculty at George Peabody College for Teachers in Tennessee where he published *Introductory Psychology for Teachers*. Strong's early career also focused on research in marketing and advertising. His research in this area resulted in several publications and the book *The Psychology of Selling and Advertising* published in 1925.

As was the case for many applied psychologists of Strong's generation, World War I had a direct impact on his career. He entered the military in 1917 and served on the Committee on Classification for Personnel and as a personnel specialist with duty assignments at Camp Taylor, Kentucky, and Camp Kearny, California. Strong's work with the Committee on Classification led him to appreciate the efficacy of the Army tests for predicting a person's ability to do a job and to understand the need for career guidance.

After his military service, Strong was on the faculty of the Carnegie Institute of Technology where he participated in a faculty–graduate student proseminar run by Clarence Yoakum, which spawned several attempts

by others (e.g., Bruce Moore, J. B. Miner, Max Freyd) to develop instruments to measure vocational interests. When the applied psychology program at Carnegie was dissolved in 1923, Strong moved to Stanford University where he taught courses in business administration, conducted research on the opportunities for Asian Americans in the United States, and eventually was encouraged by his student, Karl Cowdery, to pursue research in interest measurement.

### Contributions to Interest Measurement

Strong published the first version of the Strong, the Vocational Interest Blank, in 1927, and from that time forward his research and publications were almost exclusively in test construction and interest measurement. Throughout his time at Stanford, Strong had connections with the faculty at the University of Minnesota where the foundations of vocational guidance and the trait-and-factor theory of counseling were emerging in response to veterans returning to college. Strong became friends with Donald G. Paterson, one of the two founding faculty members of Minnesota's Department of Psychology (the other was the chair of the department, Richard M. Elliott), through the World War I Committee on Classification. His daughter, Fran Berdie Berninghausen, attended graduate school at Minnesota and later married Ralph Berdie, a faculty member. As a result, Strong occasionally spent summers teaching at the University of Minnesota, visited Minnesota after his retirement to discuss revisions of the Strong, and gave the Walter Bingham Lecture (Satisfaction and Interests) at Minnesota in 1958.

Strong's first publication on interest measurement, "An Interest Test for Personnel Managers," appeared in the *Journal of Personnel Research* in 1926. The first Strong booklet appeared in 1927, and the first manual in 1928. From the start, Strong was interested in the application of interest measurement to career decision making. For example, he wrote in the 1928 manual, "if he [sic] scores high in both law and engineering, he might prepare for both and become a patent attorney, or a lawyer specializing in engineering problems" (p. 2). He also was concerned about evidence of validity for the Strong, acknowledging in the same manual that it will be "some time before the validity of this test can be exactly determined" (p. 2). By 1929 he had published an article that demonstrated

the diagnostic value (i.e., predictive validity) of the Strong, and in 1930 he published a test-retest reliability study that spanned 1.5 years. He also worked with Louis L. Thurstone to find a meaningful way to group the scales using a method of constellation analysis that Thurstone had developed.

Strong's research in interest measurement was a combination of work to revise, improve, and expand his interest inventory and research designed to understand the construct of vocational interests. He published the first women's version of the Strong in 1935, the first major revision of the men's form in 1938, and the first major revision of the women's form in 1946. Additional revisions of the separate-sex Strong, published in 1966 (Men's Form) and 1969 (Women's Form), were developed at the University of Minnesota in consultation with Strong.

In addition to the interest inventory manuals and *Introductory Psychology for Teachers* (1922), *The Psychology of Selling Life Insurance* (1922), *Job Analysis and Curriculum* (1923), *The Psychology of Selling Advertising* (1925), *Japanese in California* (1933), and *Psychological Aspects of Business* (1938), Strong published four books on vocational interests. The first, *Change of Interests With Age*, was published in 1931; *Vocational Aptitudes of Second Generation Japanese in the United States* appeared in 1933; *Vocational Interests of Men and Women* in 1943; and *Vocational Interests Eighteen Years After College* in 1955. These books elaborated on the evidence of reliability and validity for the Strong that Strong himself collected, and the volumes of data presented in each book also provided enormous knowledge about the construct of vocational interests. *Vocational Interests of Men and Women* was published only 15 years after the first Strong inventory was published, yet it is 746 pages long, contains 197 tables and figures, and reports well over 20,000 numbers (e.g., means, standard deviations, correlations) representing thousands of research participants. This book would be an amazing accomplishment even today with the assistance of high-speed computers to crunch the numbers, but it was a phenomenal accomplishment in 1943 when only about six answer sheets could be scored per hour. The 1955 book was a longitudinal study with Stanford University students.

Strong was described by his daughter Fran as an introverted yet socially skilled person who enjoyed the people with whom he worked but also relished his time alone. His research was supported primarily by

scoring fees for tests that people would send to him. His daughter also indicated that he did much of his research at home, where there were no distractions, with the assistance of his two daughters, Fran and Margaret. He often spent the afternoons playing golf or bridge after teaching in the morning and lunching at home. Strong even interjected his interest in golf into his scholarly writing, noting that the correlation of golf scores between the first and second 18 holes in championship play usually is about .30.

John G. Darley, a University of Minnesota faculty member who knew Strong through his summer visits to the Twin Cities of Minneapolis–St. Paul, described him as a grizzly bear who was not hesitant to express his opinions. Darley also reported that Strong himself claimed never to be a theorist but rather a dirty-handed empiricist who even as he worked to develop a theoretical frame for his interest inventory was always ready and eager to go out and collect more data.

## STRONG INTEREST INVENTORY

---

The Strong Interest Inventory, published by CPP, Inc., and commonly referred to as the Strong, is one of the most widely used and scientifically grounded tools available for assessing people's career and life interests.

The Strong measures an individual's work and personal interests and compares them to those of people employed in a wide range of occupations. It is used to help people match their interests with compatible occupational, educational, and leisure pursuits. The 2004 edition of the Strong is the product of many years of research that began in 1927 with the research of E. K. Strong, a military psychologist and an academician at Stanford University. The original Strong was titled the Strong Vocational Interest Blank (SVIB), and it consisted of occupational scales that were constructed through comparing item responses from individuals working in particular occupations with item responses of a general reference sample. The SVIB became the first formal interest inventory to be published. At that time, only male samples were used, and in 1933 the first Women's Form of the SVIB was published. Eventually, in 1974, the Men's and Women's Forms were combined; Holland's six dimensions were integrated to provide an organizing structure; and the name was changed to the Strong-Campbell Interest Inventory. Several revisions followed, resulting in additional scales and improved psychometrics. In the 1980s the name of the inventory was changed again, to the Strong Interest Inventory, which remains its current name. The Strong has been updated regularly to reflect changes in the culture of the U.S. workforce and to adapt to shifting career trends. It continues to be one of the leading inventories used by counselors in a variety of settings, including colleges, high schools, career development centers, and business organizations.

### Administration and Interpretation

The Strong requires at least an eighth-grade reading level and fluency in English. It is not appropriate for individuals under the age of 13, and typically is not administered until an individual has reached the age of 16 or 17. The Strong assessment comprises six sections of items with a total of 291 items, each with a 5-point response option (*strongly dislike*, *dislike*, *indifferent*, *like*, and *strongly like*). Individuals' responses are compared to a large general sample of working men and women (2,250 people) who generally are representative of the racial and ethnic diversity of the U.S. workforce.

Administration typically takes between 30 and 45 minutes. Individuals can complete the Strong online through the publisher's SkillsOne Web site

(www.skillsone.com) or manually using mail-in scoring forms. The resulting 9-page Strong Profile is sent to the counselor, not directly to the client. The publisher offers a number of tailored reports and Strong Profile options, such as the Strong College Profile, Strong High School Profile, and Interpretive Report, to tailor results to specific populations and needs. For example, the Strong College Profile provides a 4-page supplement to the profile to help both client and counselor connect the results to college majors, college courses, and campus activities that correspond to the client's top interests.

Counselors need to demonstrate coursework in psychometrics or test interpretation (or to complete a workshop endorsed by the publisher) to qualify for ordering the Strong. The publisher offers a wide array of support materials to assist with interpretation. Both the manual and the several user's guides offer detailed instruction for interpreting various types of profiles with individuals and groups.

### Profile Description

The Strong Profile presents an individual's interests through four sets of scales and uses John Holland's theory of six vocational personality types as an organizing structure. The four sections include the following: the General Occupational Themes, the Basic Interest Scales, the Occupational Scales, and the Personal Style Scales. In addition, a number of administrative indexes are provided to help the counselor detect any unusual response patterns. An individual's scores are compared to both men and women samples, but the majority of scores on the profile draw attention to comparisons with samples of the individual's same gender.

#### **The General Occupational Themes**

The General Occupational Theme scales measure broad interest patterns used to describe an individual's work personality. They comprise items with content corresponding to Holland's description of the six occupational-personality types: Realistic, Investigative, Artistic, Social, Enterprising, and Conventional. Definitions of the themes are provided on the profile. Higher scores result from *like* and *strongly like* responses to items that relate to each of the six themes, and lower scores result from *dislike* and *strongly dislike* responses to these items. The six themes are presented in rank order of interest level on

the individual's profile using interpretive comments that compare the individual to a reference sample of the same gender. These comments range from *very little* to *very high* interest. Standard scores, which compare the individual to a reference sample of both genders, are then used to further rank-order any interpretive comments with similar values. Individuals are given a Summary Code that highlights the combination of the individuals' highest scoring themes to encourage exploration of two or three themes rather than to one alone.

#### **The Basic Interest Scales**

Thirty Basic Interest Scales measure more focused interest areas using the same construction and scoring methods as the ones used for the General Occupational Themes. These scales, such as Culinary Arts, Law, and Office Management, are grouped on the profile according to the six themes. They can be used to break down the General Occupational Themes into specific interest areas related to work, school, or leisure activities that the individual is likely to find interesting and rewarding.

#### **The Occupational Scales**

The Occupational Scales include 122 scales that represent a wide range of occupations representing all six themes. These scales measure how similar an individual's interests are to those of people of the same gender who have been satisfactorily employed in a particular occupation. Scores reflect a comparison of both the dislikes and the likes of an individual with the dislikes and likes of satisfied workers sampled from that occupation. Consequently, the higher the score, the more the individual shares similar interests and disinterests with people from that occupation. The profile highlights the 10 occupations most closely aligned with the individual's interests, and scores are presented for each of the 211 scales using a bar graph that extends from dissimilar to similar. The profile shows only comparisons with samples of the individual's same gender (unlike previous editions of the Strong, which included comparisons to both genders).

#### **The Personal Style Scales**

The five Personal Style Scales describe different ways of approaching work, learning, leadership, risk taking, and team participation. Unlike all other scales

on the Strong, each of the Personal Style Scales is presented as a bipolar continuum and describes the individual's preference for one style versus another in comparison to a reference group of men and women combined. Scores are labeled as *clear* when they fall toward either polarity of the continuum, and as *midrange* when they fall toward the middle. Descriptors are provided at each end of each continuum providing examples of a preference for one style versus the other. For example, the first Personal Style Scale, Work Style, describes scores toward the left pole as "Prefers working alone; enjoys data, ideas or things; reserved," and scores toward the right pole as "Prefers working with people; enjoys helping others; outgoing."

### Profile Summary

A summary page is provided on the last page of the profile. This page summarizes the individual's highest themes, top five specific interest areas, top 10 occupations, and each Personal Style Scale preference. The areas of least interest to the individual also are summarized here. The purpose of this page is to help the individual focus on common interest themes that are consistent throughout the profile.

### Research and Practice

The Strong is one of the most extensively researched inventories available. The developers engaged in significant research to support the current edition, and numerous scholars have published a large body of literature to support the instrument throughout its history. The *Strong Interest Inventory Manual* provides detailed descriptions of the research that led to item selection, scale construction, reference sample collection, and scoring. Evidence for both the validity and reliability for each set of scales on the Strong is impressive and provides strong support for confident use of the Strong with a variety of client populations. Used appropriately, it serves as a dependable tool for helping clients make informed career, academic, and life decisions.

## SUPER, DONALD EDWIN (1910–1994)

---

There are two grand paradigms in vocational psychology. The first perspective for understanding vocational behavior concentrates on how individual differences in ability and interests relate to occupational requirements, routines, and reward. This paradigm, called the *matching model*, asserts that the goodness of fit between an individual's abilities and a job's requirements determines the worker's occupational success. Furthermore, the match between the individual's interests and the job's rewards determines the worker's job satisfaction. Workers who are successful and satisfied with their routines, in other words adjusted, remain in the job for long periods of time, thus achieving occupational stability. This paradigm lies at the heart of professional activities such as vocational guidance, personnel selection, and military classification.

In the 1940s, Donald Edwin Super made two major contributions to the matching model for understanding vocational behavior. In 1942 he published *The Dynamics of Vocational Adjustment*, which described his views on vocational guidance. In 1949 he published an encyclopedic tome, *Appraising Vocational Fitness by Means of Psychological Tests* that analyzed the data on the use of tests in vocational guidance and personnel selection. These two contributions secured his stature as a prominent vocational psychologist, and accordingly in 1949 he was promoted to the rank of professor of psychology and education at Teachers College, Columbia University where in 1940 he had earned

his Ph.D. under the sponsorship of Harry Dexter Kitson and where he worked from 1945 to 1975.

Following his promotion to the rank of professor, Super became more interested in theory construction than in the application of psychology to personnel selection and vocational guidance. A stinging critique of vocational psychology had been published in 1951 by Eli Ginzberg who in effect asserted that the discipline of occupational psychology had been operating without a theory. This critique ushered in the theory building era of vocational psychology during which John Lewis Holland in 1959 consolidated the voluminous research and reflection on the matching model into an elegant theory of vocational personality types and work environments. Super took a different tact. He turned his attention away from how individuals differ from each other in abilities and interest. Instead he concentrated on how an individual differs from himself or herself across time, that is, how individuals develop their careers.

The 1950s was a decade during which hierarchical corporations rose in urban centers of America. The bureaucratic structure of corporations created career paths along which individuals could grow in occupational responsibility and income. Career came to be viewed as the value accompanying bureaucratic form. Rather than remaining in one job for life, many individuals could envision progressing along a predictable sequence of positions. Super became the leading architect of vocational psychology's response to the new social arrangement of occupational lives into career patterns. He added a career development model to the longstanding occupational matching model. His developmental model of how a career progresses over the life cycle became the second major paradigm in vocational psychology, one that, paired with Holland's theory, dominated the field of vocational psychology during the second half of the 20th century.

The first major statement of Super's career development model appeared as a 1953 article titled "A Theory of Vocational Development." This article, published in the *American Psychologist*, presented 10 propositions in what would become known as Super's theory of career development. The conclusions sketched in that article were elaborated in Super's celebrated 1957 textbook titled *The Psychology of Careers*, a title he purposefully selected to highlight the contrast with Anne Roe's 1956 book titled *The Psychology of Occupations*. Dedicated to Kitson, the 1957 book documented the conclusions that Super drew from his decade-long study of careers.

One seminal contribution reported both in his 1953 article and in his 1957 book was a model of career as a sequence of stages. Super conceptualized careers as unfolding in an orderly sequence that begins with a growth stage (ages 4–13) during which an individual formulates a vocational self-concept and rehearses relevant abilities and interests. During the exploration stage (ages 14–25), these occupationally relevant traits are first crystallized during adolescence and then translated into a specific occupational choice that is tried on during early adulthood. After several years of trial and tentative moves, the individual stabilizes into an occupational position. During the establishment stage (ages 26–44), the individual first stabilizes in the position, then consolidates that position through productive and dependable work. If opportunities present themselves, the individual may advance to positions with more responsibility and income. At some point, advancement slows or even terminates, and the individual maintains the success and stature he or she has achieved. During the maintenance stage (46–65), the individual holds onto the position, hopefully by updating and innovating how it is done. The final stage in the sequence is called disengagement because the individual decelerates work activity and gradually turns responsibilities over to younger colleagues as he or she prepares for retirement and in due course begins retirement living.

Implicit in Super's stage model of career development lies the construct of maturity. Career maturity means possession of the readiness and resources needed to cope with the developmental tasks inherent in each career stage. Mastering these tasks, which can be viewed as social expectations, develops the individual and leads to increased success and satisfaction. Difficulties in adapting to these tasks result in failure and frustration. Super conducted a 30-year longitudinal investigation called the Career Pattern Study to examine how adolescents cope with the career development tasks of the exploration stage.

He conceptualized three tasks to linguistically explain the exploration stage. The first task was to crystallize general preferences for a group of occupations at a similar ability level and within similar fields of work. After broad exploration of these general preferences, the individual must select a few for in-depth exploration and finally specify an occupational choice that implements his or her self-concept in a work role. The third task of the exploration years is to convert that occupational choice into a reality by securing a position in the chosen occupation. The initial years in

the chosen occupation are considered a period of trial because the choice is still tentative until the individual decides to stabilize in a position. During the trial period individuals may drift between positions and even flounder in a job or two before stabilizing. This movement is preferable to stagnating, which means stabilizing in a poorly fitting position.

Progress through the tasks of crystallizing preferences, specifying a choice, and implementing that choice can be used to index an adolescent's career maturity. Super conceptualized maturation as dealing with age-appropriate tasks. He viewed career maturity as handling the tasks as well as one's peer group. To examine how well individuals handle the tasks, Super crafted a model of career maturity during adolescence. He operationally defined this model with an instrument known as the Career Development Inventory.

Super's model of career maturity, or career choice readiness, has five components. The fifth component is called realism and occurs later in adolescence or early in adulthood. Thus, he does not use realism in indexing the career maturity of adolescents. The other four dimensions of maturity are divided into two groups. The first two dimensions are attitudinal, and the second two dimensions are cognitive. Super viewed looking ahead and looking around as two critical coping behaviors. Therefore, he conceptualized attitudes toward planning for the future and toward exploring possible selves and occupational opportunities as the two key dimensions in his model of maturity. Knowing what choices need to be made and having explored self and occupations, the individual must apply the resulting fund of information in making life-shaping decisions. Accordingly, the two cognitive dimensions or competencies in the maturity model are information about occupations and skill at making decisions. Stated simply, the idea is that individuals who have planned ahead and explored possibilities have the information required to make fitting decisions in choosing an occupation. Typical variations in the development of these attitudes and competencies lead to predictable problems including unrealism and undecidedness, whereas atypical deviations in their development lead to severe difficulties including apathy and indecisiveness.

Near the end of his own career, Super realized that the social organization of the work was radically shifting as the world began the age of globalization and digitalization. No longer can an individual expect to work 30 years for one employer, progressing along a

predictable career path until it is time to draw a pension. Contemporary workers can expect to occupy 10 or more positions during their careers. Super addressed the decline of organizational careers by explaining that his model of career stages, with minimal modifications, fit the postindustrial career if it is viewed as a sequence of tasks through which individuals recycle as they move from organization to organization and from job to job. Thus, an individual at age 45 who, after working in a job for 10 years, loses that position to outsourcing then needs to recycle through the tasks—not stages—of growth in awareness of new opportunities, exploration of these possibilities, transition to a new position and stabilization in it, followed by a period, say 5 to 7 years, of maintaining or managing that position before disengaging from it and recycling through the tasks once again.

## SUPER'S THEORY

---

Beginning with the first documented vocational counseling attempts of Frank Parsons in 1909, vocational counseling and research focused for nearly half a century on vocational choice—not on how or why one made a particular vocational decision, but rather on what that decision was. Donald Super's theory of

vocational development was therefore unique in being one of the first attempts to explain the process underlying vocational choice and to take a developmental perspective by looking at vocational development across the life span.

In developing his theory, Super drew on the earlier work of Eli Ginzberg, Sol Ginsburg, Sidney Axelrad, and John Herma, who presented a model of vocational choice as part of a developmental process and incorporated Charlotte Beuheler's concept of life stages. Therefore, at the core of Super's theory has always existed the idea of five predictable stages of vocational development that occur as part of a continuous process throughout the life span. The theory was tested and refined based on results from the Career Pattern Study. This large-scale longitudinal study followed the career development of a large group of boys from Middletown, New York, who were in the eighth and ninth grades in 1951. Although the culturally homogenous nature of this sample has led to concerns about the cultural validity of Super's theory, the Career Pattern Study remains one of the most ambitious studies of vocational development.

Super developed and refined the theory over the decades since it was first proposed. His final formulation of the theory, referred to as the life-span, life-space approach, is captured by two models: the life-career rainbow and the archway of career determinants.

### **The Life-Career Rainbow**

According to Super, a career consists of the varying roles people take on during their lives. The life-career rainbow (or career rainbow model) brings together both the roles played in life (the life space) with the five developmental stages or structures of life (the life span).

#### ***Life Space***

Super believed that people play several roles during a lifetime, with the work role as one of many. These roles are included in the life-career rainbow in what is called the life space. Life space is captured in the horizontal arches of Super's rainbow and contains the roles of child, student, leisurite, citizen, worker, and homemaker. Roles can be enacted simultaneously, as when, for example, an individual has an active career, is a parent, and is active in community organizations. Roles that take more time commitment become more central, whereas other roles involving

less commitment become more peripheral. People are defined by the central roles they play. As life transitions occur, central and peripheral roles are changed, added, or dropped. For example, the child and student roles become more peripheral as one becomes established with career and family. Similarly, increasing the number of roles in one's life may mean less commitment to other roles. Roles can also interact, with outcomes in one role affecting outcomes of other roles. Depending on these interactions and the amount of energy and time taken from other roles, the presence of multiple roles may be positive or negative.

#### ***Life Span***

As noted above, the roles played by a person develop and change throughout the course of a lifetime. The life span, symbolized by the top layer of the life-career rainbow, signifies the developmental structure in which the individual adapts to work. This layer shows a progression of life stages, from childhood to old age, that correspond to Super's five career development life stages: growth, exploration, establishment, maintenance and disengagement. Each stage comprises several key career tasks that the individual is challenged to master before progressing to the next stage. Vocational or career maturity refers to how well an individual is able to handle these tasks.

### **Developmental Stages**

During the growth stage, ages 4 to 13, the person achieves the initial steps toward career development, which range from simply caring about a vocational future to achieving appropriate attitudes and behaviors toward work. During this stage, children develop their self-concept as they explore their environment and meet important adult role models. If children encounter a sufficient variety of rewarding experiences during this stage, they will develop not only interests, but autonomy, self-esteem, and a sense of the future as well. A lack of rewarding experiences hinders such development. Thus, children may become innovative or conventional, goal-oriented or purposeless as a result of the learning they encounter in this stage. This growth stage contains the three sub-stages: fantasy, interest, and capacity. Children begin to develop by fantasizing through role-plays, they then develop interests by liking certain tasks over others, and finally they begin to consider their abilities in relation to job requirements.

In the next stage, exploration, which occurs between the ages of 14 and 24, the developmental tasks are to narrow vocational interests in order to make a vocational choice. Open exploration becomes focused, allowing individuals to enact their private views of themselves into a career choice or educational decision. For example, adolescents begin trying out various part-time jobs, and students declare a major in college that is consistent with their interests. During this stage, one may choose a career early without examining other options; such foreclosure may lead to later vocational discontentment. The exploration stage contains the substages of tentative, transition, and trial. Individuals tentatively form decisions in regards to their needs, interests, and abilities and then encounter transition as they move into the reality of the world of work; finally individuals enter a field of work and test the job for its appropriateness, given their needs and abilities.

Once a suitable field of work is chosen, the person enters the establishment stage, ages 25 to 44, in which the salient tasks are to keep and advance in the job. This is done by becoming part of the organizational culture, demonstrating adequate job performance, and getting along with one's colleagues. Success in these tasks then may allow the individual to advance within his or her career.

During the maintenance stage, ages 45–65, individuals face the tasks of maintaining their place at work in the face of changes and competition from younger, more eager and educated workers. This may involve gaining new skills and becoming more aware of current trends; without doing so, one may experience stagnation in one's career.

In the final stage, disengagement, which usually occurs after the age of 65, individuals face the career tasks of disengaging from the work role and planning for and living in retirement. Disengagement from work often occurs due to age-related declines in mental and physical capacities. Such disengagement may be seen by engineers who begin to take on fewer projects or by professors who choose to teach fewer classes. This deceleration may then lead to retirement, in which occupational activities are ceased.

### Maxi- and Mini-Cycles

According to the life-career rainbow, these five stages of development occur in order in what is called a *maxi-cycle*. Future vocational problems may occur when one does not follow the proposed order of

stages. For example, foreclosing early without proper exploration can lead to a less suitable occupational choice. The theory also recognizes that transitions between stages and career interruptions often lead individuals to experience a *mini-cycle* or a recycling through stages. For example, an adult in the maintenance stage of a maxi-cycle might find that with a promotion come the needs to explore new skills and establish new roles with coworkers. Alternately, adults in this stage who lose their job may be forced to recycle through earlier stages and reexplore interests and values to select a new career and then reestablish themselves in the new field.

### The Archway of Career Determinants Model

Explicit in Super's developmental tasks are the ideas (a) that individuals possess different abilities, interests, values, and so on; (b) that these patterns of intrapersonal characteristics make individuals more or less suited to different careers; and (c) these individual differences and the careers available to a person at any one time are shaped by situational factors. Super's second synthesizing model, the archway of career determinants, was created to make more explicit these environmental and intrapersonal determinants of career that are suggested by the developmental tasks of the career rainbow model. Thus, the arch is similar to the rainbow in that it describes Super's career development theory but differs in how it is described.

As its name suggests, the archway model is shaped in the form of an arch, which represents an individual's career. Each stone of the arch symbolizes an influential factor or determinant of career. The most basic determinants are near the base with biology and environment forming the bottom of the base. An individual's personality characteristics (e.g., intelligence, needs, values) form the column on the left. Societal characteristics (e.g., labor market, school, family) form the column on the right. Although not represented graphically, these intrapersonal and environmental factors are assumed to interact with each other in determining an individual's career development. The arch itself sits on these two pillars and signifies the outcomes of the two columns of personality and societal determinants. The two ends of the arch represent the developmental stages, with the left side containing the earlier developmental stages and the right side containing the later stages. Finally the arch culminates to form the keystone, the central piece of the

arch, which represents the person who makes the career decisions.

### Career Development Assessment and Counseling Model

In addition to these well-articulated theoretical models, Super developed counseling applications of these models. His career development assessment and counseling model integrates several useful assessment instruments to explore a client's development, values, interests, and career maturity. Several sequences are possible, but often assessment begins by determining where the client is in the life space, life span, and what the importance of the work role is. The latter may be done with adolescents and young adults using the Career Development Inventory (CDI) or with older adults using the Adult Career Concerns Inventory (ACCI). The CDI measures career decision-making readiness by assessing career decisions in light of the attitudes and knowledge possessed by the adolescent or young adult. The ACCI measures concerns and planning related to the career developmental stages of exploration, establishment, maintenance, and disengagement. The Salience Inventory may be used to assess how important a life role is to an individual in comparison to other life roles. Five life roles (student, worker, citizen, homemaker, and leisurite) are assessed in regards to activity, dedication, and value expectations. If assessment reveals that the work role is not very important, then the counselor may either attempt to better orient the client to the work role or shift the focus from vocational development to development of other roles, depending on the appropriateness of the lack of work role salience. This assessment may also reveal useful information about the interactions among the individual's varying roles. Assessment then proceeds to measuring the client's interests and values, using common tools such as the Strong Interest Inventory and the Values Scale, which assesses 21 intrinsic and extrinsic work values individuals may seek to satisfy within their life space. Often these values underlie the individual's interests, as when, for example, values of altruism are reflected in social interests. Finally, these assessment results are integrated into a narrative interpretation that identifies needed areas of growth (e.g., in work-related attitudes or acquisition of new skills) and suggests ways that counseling may help in such development.

### Criticisms and Future Directions

In the archway model, the column representing situational determinants is equal in size and, ostensibly, importance to the column representing personal career determinants. However, as suggested by the person as keystone, Super's theory is held together by the central salience of the individual. The better able people are to match their interests, values, needs, and abilities to an occupation, the more likely they are to have a satisfying and productive career. This fundamental premise that a successful career choice depends on successful implementation of the self-concept underlies the most significant criticism of Super's theory: that it overemphasizes the role of the individual and underestimates the role of the environment and culture. For example, although Super's theory clearly acknowledges situational determinants of career, some have argued that the theory does not adequately acknowledge the impact of discrimination and circumscribed opportunities faced by many persons of color and others. In addition, the emphasis on individual choice fails to acknowledge the important role of the family or group for individuals from more collectivist cultures or with a more interdependent sense of self, such as Asian Americans.

Despite these criticisms, which Super himself acknowledged, his theory of vocational development remains one of the most influential approaches to understanding vocational development. His developmental approach moved the focus from a one-time adolescent or young adult career choice to an understanding of the multiple influences from birth through death that shape a lifetime of career behaviors. Furthermore, the theory has clear counseling applications. Although aspects of the theory may need to be modified when applied with clients from some cultural groups, Super's developmental approach to understanding career behavior across the life span, refined across several decades, remains of tremendous relevance. Future directions that would increase the relevance and utility of the theory include greater attention to cultural context and to development in the later stages.

## SYSTEM OF INTERACTIVE GUIDANCE INFORMATION

---

The System of Interactive Guidance Information (SIGI) is a computer-assisted career guidance system (CACGS) for university students and adults. It is a computer program designed to help people make informed career decisions via self-assessments and in-depth, current educational and job information. The program also has an educational aspect that teaches users about the career decision-making process. SIGI provides users with realistic choices for educational and career options that are likely to best suit them

based on self-assessment results that are matched to fields of study and occupations that are held in databases that are accessed by the program. SIGI is a career exploration tool students may use to determine how their interests, values, and skills relate to a wide variety of career fields, as well as the education, skills, and background required for these fields.

### History

Donald Super, David Tiedeman, and Martin Katz explored early ideas about computer use in career development in the 1950s and 1960s. SIGI is a computer program that was developed by the Educational Testing Service (ETS) based on Martin Katz's career decision-making theory and was originally released in 1970. SIGI was one of the first computer products of its kind. When ETS introduced SIGI in 1970, the company offered computerized career information and guidance to community colleges, 4-year colleges, and universities across the United States.

During the mid-1980s, SIGI became SIGI PLUS when it was reprogrammed for microcomputers and other enhancements were added. The program was modified for use with Microsoft Windows in 1996, and in 2001 ETS developed the first Web-based version. ETS upgraded and enhanced SIGI over the years, and SIGI PLUS operated both on the Internet and on personal computers.

Valpar International has been creating and marketing vocational assessment instruments since 1973. In July of 2004, Valpar acquired SIGI PLUS from ETS in order to expand its selection of career exploration software. On May 30, 2005, Valpar replaced the Internet version of SIGI PLUS with SIGI<sup>3</sup>, which is a revision of SIGI PLUS that has been updated and expanded. SIGI<sup>3</sup> is a Web-based version of SIGI PLUS that maintains the content and philosophy of the older version, but it provides a more updated and efficient interface. Features of SIGI PLUS remain or have been enhanced, and navigating the software has been made easier. Valpar will be adding features such as a new look to the screens, a more intuitive user interface, improved navigation, expanded occupational database, enhanced student portfolio, management reports, additional assessments such as a personality trait survey, video library, publicity kit, and other changes, but Valpar will not change the values-based career exploration foundation of SIGI PLUS.

## **Review of the SIGI Literature**

SIGI PLUS quickly became one of the leading three career guidance systems on the market in terms of sales and popularity. However, research supporting the effectiveness of SIGI, SIGI PLUS, SIGI<sup>3</sup>, and other CACGSs is relatively scant. These interventions have been utilized with numerous career clients, despite having relatively little research support for their efficacy. Approximately 22 citations related to either SIGI or SIGI PLUS can be found. No recent or research articles on SIGI<sup>3</sup> were found on Valpar's Web site or elsewhere.

### ***Satisfaction With SIGI***

Over the years, a number of researchers have attempted to compare user satisfaction with SIGI to satisfaction with other CACGSs and career counseling methods such as individual and group career counseling.

#### **Comparison of SIGI With Other CACGSs**

When compared with other CACGSs, students and counselors have rated SIGI highly in terms of satisfaction, specifically regarding the program's helpfulness and appeal. Users have expressed satisfaction with both SIGI and SIGI PLUS programs, which in their times have historically been popular and were commonly used CACGSs.

#### **Stand-Alone SIGI Versus SIGI and Individual Career Counseling**

There has been a long-term debate in the literature about how SIGI and other CACGSs should be utilized. Some authors suggest that SIGI can be used as a stand-alone career exploration tool; others argue that career counseling in addition to use of the program enhances outcomes. Some authors have examined whether or not traditional counseling intervention is required to maximize the effectiveness of SIGI use. Multiple studies have indicated that students prefer using SIGI when individual counseling is available as a follow-up to their experience with the program. Counselors thus seem to be a vital and desired component of the computer-assisted guidance process.

A separate question is whether or not SIGI affects changes in career development and decision making. It is this issue to which this entry will now turn.

## ***Effectiveness of SIGI***

A number of studies have examined the effectiveness of SIGI. Overall, SIGI has demonstrated significant positive changes. For example, SIGI users have shown significant positive changes on measures of decision-making stage related to occupation. Brief exposure to SIGI can also have positive effects related to choice of a college major. SIGI's approach to career exploration might create the excitement and motivation needed to facilitate concentration and attention of new users. SIGI also is an individualized approach that is adaptable to user needs, providing personal attention and information to the user.

#### **SIGI Versus SIGI PLUS**

Students have found SIGI and SIGI PLUS to be equally helpful for obtaining information about themselves and the world of work, effectiveness in suggesting career options, and appeal of using a computer for career exploration. Students tend to prefer using SIGI PLUS to SIGI. However, no differences in impact have been found, even when potential moderator variables have been taken into account. Users rated the systems comparably in terms of self- and occupational assessment, generation of options, and general helpfulness, regardless of other factors such as their scores on career decidedness, vocational identity, perceived barriers, information needs, or year in school.

#### **SIGI Versus Group Career Counseling**

Multiple studies have compared the effects of SIGI with group career counseling, with mixed results. At times, both interventions have been found to be effective; at others, only SIGI produced positive results. Regardless, SIGI appears to have a consistently positive impact on career development of users.

#### **SIGI and Individual Career Counseling**

SIGI alone has been found to be somewhat effective in enhancing career outcomes. However, many individuals using SIGI desire access to the combination of SIGI and individual career counseling. There is also some indication that users find that a combination of SIGI and counseling is more beneficial in meeting their needs than SIGI alone.

## The Future of SIGI

More than 30 CACGSs have been developed in the past few decades. However, many of these systems have become obsolete or are simply not commonly used. SIGI seems to have stood the test of time by going through multiple revisions and further enhancements and adaptations for use with current computer technologies. Given its long history and apparent revitalization by Valpar, there appears to be a place for SIGI in the career development of university students and adults in future years to come. SIGI will need to be kept up to date and relevant to remain a competitive product. This seems likely given that Valpar has committed to revising the program regularly, rather than just once a year as it has been in the past.

## THEORY OF WORK ADJUSTMENT

---

The Theory of Work Adjustment (TWA) is a person–environment fit (P–E fit) theory that elaborated the P–E fit theories of Frank Parsons, Donald G. Paterson, and John G. Darley into a dynamic model of vocational adjustment. The TWA postulates that optimal vocational outcomes occur when (a) the individual’s abilities match the skills required for success in the occupation and (b) the individual’s needs are satisfied by the occupation. This match between the worker and the occupation, referred to in the theory as correspondence, results in good work adjustment. The TWA specifies the components that are important determinants of correspondence and the dynamic process by which correspondence develops and is maintained.

### Development of the Theory

Development of the TWA occurred in two distinct phases. During the 1960s, Lloyd H. Lofquist and René V. Dawis, University of Minnesota psychologists, formulated a trait-and-factor matching model and in collaboration with David J. Weiss developed instruments to measure the major constructs introduced by the theory. The initial statement of the theory in

1964 provided the conceptual framework for the continuing program of research undertaken by the Minnesota Work Adjustment Project (WAP) from 1964 to 1972. The publication of *Adjustment to Work* 4 years later marked the culmination of this phase of theory building.

Elaboration of the theory continued along two fronts during the 1970s. First, the authors bridged the theoretical gap between vocational needs and work values. Of greater significance, however, was their elucidation of their constructs of personality style and work environment style and the dynamics of the work adjustment process. Integration of the structural and dynamic aspects of the theory during the 1970s transformed the TWA from a static trait-and-factor model to a developmentally oriented model that describes the ongoing interaction between individuals and their work environments.

### Structure of Work Adjustment

According to the TWA, work adjustment is a function of the correspondence (i.e., quality of the match) between an individual’s work personality and the work environment. The work personality consists of the psychosocial needs and abilities of the worker. The salient attributes of the work environment are the rewards provided by the job and the skills required to perform the work tasks successfully. A good match (i.e., work adjustment) results in job satisfaction, satisfactory job performance, and worker tenure. A poor match leads to worker dissatisfaction, poor job performance, and turnover.

Each worker has a unique set of psychological (i.e., secondary or learned) needs. The TWA and the research program it inspired identified 21 needs (i.e., learned preferences for particular stimulus conditions) that influence the individual's reaction to a particular occupational environment. These are ability utilization, achievement, activity, advancement, authority, company policies, compensation, coworkers, creativity, independence, moral values, recognition, responsibility, security, social science, social status, supervision–human relations, supervision–technical, variety, working condition, and autonomy. The WAP developed the Minnesota Importance Questionnaire (MIQ) to measure the importance of each of these needs to the individual.

Each work environment satisfies some of these needs, but not others. For example, the job of elementary school teacher satisfies the needs to make use of your abilities, try out your own ideas, and help others, but it provides little opportunity to tell other workers what to do or to be paid well in comparison to other workers. The degree to which the occupation satisfies the worker's needs determines the degree of correspondence, or more generally the degree of P–E fit. The WAP developed the Minnesota Job Description Questionnaire (MJDQ) to use in determining the rewards provided by an occupation. The pattern of rewards provided by an occupation (i.e., the profile of scores) is called the Occupational Reinforcer Pattern.

The other attribute of the person that forms the work personality is the worker's set of skills and abilities. Examples of job-relevant skills include verbal fluency, manual dexterity, and numerical comprehension. Psychology has focused on ability measurement since the beginning of the 20th century, so it was not necessary for the WAP research scientists to develop a separate instrument to measure worker ability. Broad-band instruments such as the General Aptitude Test Battery (GATB) and narrow-band instruments such as the Number Comparison test of the Minnesota Clerical Test are used to measure worker skills and abilities.

Each occupation requires certain skills for success. Workers who do not have the abilities required by an occupation will not be able to perform well in that work environment. For example, an individual with good verbal skills but poor eye–hand coordination would most likely be successful in a different set of occupations than a worker having the reverse pattern of strengths and weaknesses. The requirements of the work environment can be as simple as the ability to

stack cases on a pallet or as complex as the ability to solve mathematical equations. The better the skills of workers match the requirements of their work environments, the better they can perform their jobs. Performance is termed *satisfactoriness* in the TWA.

The U.S. Employment Service had published data, based on results obtained using the GATB, for more than 1,200 occupations grouped into 62 Occupational Aptitude Patterns (OAP). The WAP scholars developed the Minnesota Job Requirements Questionnaire (MJRQ) for use in obtaining information about the skills needed for success in occupations not included in the OAP data.

### Dynamics Process of Work Adjustment

While the structural model depicted above appears to describe a static state, Dawis and Lofquist actually viewed work adjustment as an ongoing process in which the worker and the work environment continually respond to each other to maintain correspondence. They chose the term *correspondence* to indicate the degree of worker–work environment match to emphasize the responsiveness of the worker and work environment. Work adjustment is the dynamic process by which the person and work environment seek to achieve and maintain correspondence with each other. The personality style of each determines how they respond to the other. The TWA identifies four aspects of personality style.

When an individual and a work environment are not correspondent (i.e., discorrespondent) the individual could leave the work environment voluntarily (i.e., quit) or involuntarily (i.e., be terminated), or could attempt to increase correspondence with the work environment. Workers can use two *modes of adjustment* in attempting to increase correspondence. Consider, for example, workers who find it difficult to work at the same hours every day. Workers who try to increase correspondence by attempting to change their work environment (e.g., negotiate flexible working hours) are using an *active mode of adjustment*. Workers who try to increase correspondence by attempting to change some aspect of their behavior or personal situation (e.g., modifying child care arrangements) are using a *reactive mode of adjustment*. Likewise, the work environment could attempt to increase correspondence by using an active or reactive mode of adjustment.

Dawis and Lofquist refer to these as personality styles rather than as types because they do not expect

individuals or work environments to limit themselves to one or the other. The style used is a function of the specific situation and the user's judgment regarding the approach that is most likely to be successful. Dawis's and Lofquist's work on personality styles illustrates a remarkable convergence with the theoretical views of Tiedeman and Robert O'Hara and V. A. Harren regarding the developmental process that characterizes the implementation of career decisions.

A second aspect of personality style is the *degree of tolerance* displayed by the worker and work environment. Perfect correspondence between the individual and work environment is difficult to achieve and almost impossible to maintain for any length of time. Therefore, correspondence is less than perfect for most persons and work environments most of the time. *Flexible* individuals and work environments are able to tolerate a relatively high level of discordance. *Inflexible* individuals and work environments generally tolerate only low levels of discordance. Most workers and work environments fall somewhere between these polar extremes. Nevertheless, whenever the level of discordance exceeds the worker's or work environment's level of tolerance the discordance is regarded as unmanageable and action is initiated to reduce the discordance or discontinue the relationship.

The third aspect of personality style is the *speed of adjustment*. Once an individual or work environment determines that action is necessary to reduce discordance (i.e., to increase correspondence), those with a *high celerity level* (i.e., fast adjusters) move to achieve correspondence or terminate the relationship quickly. Those with a *low celerity level* (i.e., slow adjusters) move through the process at a more leisurely pace.

### Outcomes of Work Adjustment

Substantially more than 100 scientific investigations have examined aspects of the TWA. The vast majority of the research has examined the relation between worker-need, occupational-reward correspondence and job satisfaction. The results show that need-reward correspondence is positively related to job satisfaction. The greater the correspondence on a specific dimension, the more satisfied the worker is with that aspect of the job. The greater the overall correspondence between the total set of worker needs and environmental rewards, the greater the overall job satisfaction.

Several studies have examined the relation of need-reward correspondence to job tenure. In general, the results reveal a relation between correspondence and job tenure.

In summary, the matching model proposed by the TWA depicted work adjustment as a function of job satisfaction and job satisfactoriness. Job satisfaction results when the rewards provided by the occupation (measured by the MJDQ) satisfy the needs of the worker (measured by the MIQ). Job satisfactoriness results when the abilities of the worker (measured by an ability instrument such as the GATB) match the skills required for success (indicated by OAP data or MJRQ results). Tenure (i.e., longevity in an occupation) results when both satisfaction and satisfactoriness are high. Satisfied workers are more likely to remain in their jobs while dissatisfied workers are more likely to quit their jobs. Workers who perform their jobs poorly are more likely to be fired while those who perform their jobs well are likely to be encouraged to stay.

## TIEDEMAN'S DECISION-MAKING THEORY

---

David Valentine Tiedeman received his B.A. in psychology at Union College in 1941. Tiedeman would receive a master's from the University of Rochester in 1943 and go on to Harvard to complete degrees in

educational measurement both his Ed.M. in 1948 and an Ed.D. in 1949. While at Harvard, Tiedeman was mentored by the renowned statistician Philip Justin Rulon. Upon graduation, Tiedeman stayed on as a faculty member at Harvard where he remained for over 20 years. Tiedeman's theory was introduced with the publication of *Career Development: Choice and Adjustment* by Tiedeman and O'Hara in 1963. Tiedeman broke new ground in emphasizing the significance of ego development on career development, particularly career decision making. Healthy ego development resulted from maintaining mastery of crises outlined by Erikson's psychosocial theory and allowing the individual to achieve a favorable view of the self in situational contexts as well as in the larger world around the individual and eventually the world of work. Career development and career decision-making skills also developed, as the individual sought identification and acceptance of his or her evolving self through differentiation and integration. Tiedeman's theory separates the differentiation and integration of decision making into two distinct processes: anticipation or preoccupation and implementation or accommodation. Exploration, crystallization, choice, and clarification comprise the stages of anticipation, while induction, reformation, and integration comprise the stages of implementation.

Among the revisions and adaptations of Tiedeman's original theory are the works of Anna Miller and Tiedeman, Gordon Dudley and Tiedeman, John Peatling and Tiedeman, and Tiedeman and Anna Miller-Tiedeman. Tiedeman's influence can be found in the professional journal literature, text books, and career guidance curriculums. Tiedeman's theory was one of the early entries into computer-based career guidance programs with the development of the Information System for Vocational Decisions (ISVD). As a result of its own achieved identity, Tiedeman's theory would come to be recognized as one of the first constructivist based theories associated with career development. Three of the most enduring contributions of his theory are the emphasis on the role of ego identity development in career development, the role of purposeful action in dealing with discontinuities, and the significance of differentiation and integration in the evolution of career decision making.

Tiedeman's theory has been criticized for being rather complex with ill-defined terminology. There are questions as to how effectively the ISVD actually relates to Tiedeman's theory. Assessment instruments

derived from the theory, such as the Assessment of Career Decision Making by Harren, and research related to the theory itself remain limited at best. The theory also fails to adequately outline the influence of the environment outside of the individual. Finally, Tiedeman's initial sample for the conceptualization of his theory was rather small and homogeneous, thus concerns for its multicultural relevance generally follow.

Tiedeman's theory has recently enjoyed renewed recognition for its early work on meaning making and its relevance as one of the earliest contributions to the constructivist perspective. Tiedeman's spouse Anna Miller-Tiedeman remains active in her work through the New Career Institute.

## TINSLEY, HOWARD E. A. (1940– )

---

Howard E. A. (Tony) Tinsley, born July 20, 1940, in Iola, Kansas, is an internationally recognized expert on leisure and vocational psychology and a leading authority on expectations about counseling and research methodology. His more than 150 publications rank him as one of the most prolific scholars in counseling psychology. His contributions to professional psychology include service as President of the Academy of Leisure Sciences, Editor of the *Journal of Vocational Behavior*, and Chair of the American College Personnel Association Commission on Assessment. He has served on the Board of the Council of Counseling Psychology Training Programs, on the Editorial Advisory Board of the Test Corporation of America, and as Director of Doctoral Study of one of the leading counseling psychology training programs. He is a Fellow of numerous professional associations including the Academy of Leisure Sciences, American Psychological Association (APA), and Association for Psychological Science. He is a Diplomat of the American Board of Vocational Experts. Tinsley is currently professor emeritus of psychology at Southern Illinois University Carbondale (SIUC) and a professor in the World Leisure International Center of Excellence and Department of Leisure and Environment at Wageningen University, The Netherlands.

### Early Influences

Tinsley completed his baccalaureate studies (1965) and master's degree (1966) in psychology at Western Washington State College where he had the distinction of being a member of the first class admitted to graduate study in psychology. Numerous experiences during his undergraduate years sparked Tinsley's interest in leisure psychology. He served as director of

the student-owned lakefront recreational facility during his sophomore year, and he established and chaired a research advisory council that conducted extensive research on students' preferences for leisure programming. He was in charge of student-sponsored cultural, recreational, and leisure programs during his senior year. His master's thesis investigated the effects of leisure activity preferences on students' perceptions of leisure activity preferences. These early experiences in applying psychological theory and research methodology to the study of leisure stimulated his lifelong interest in the scientific study of leisure behavior.

Although doctoral students typically study under the direction of a single mentor, Tinsley studied with three renowned psychologists at the University of Minnesota. Lloyd H. Lofquist, Tinsley's official academic advisor, was instrumental in founding the American Rehabilitation Counseling Association. René V. Dawis was a brilliant theoretician whose work on the theory of work adjustment influenced Tinsley's later theory of transcendent leisure experience. Dawis's early advocacy of item response theory prompted Tinsley's selection of a doctoral dissertation topic and encouraged his lifelong interest in scale construction.

David J. Weiss was the research director of the Work Adjustment Project, which had just begun an extensive 7-year program of instrument development and research. Weiss's systematic approach to theory-based research and instrument development provided doctoral students with a meaningful laboratory in which to develop their research and scale construction skills. Tinsley's experiences under the supervision of Lofquist, Dawis, and Weiss stimulated his interest in vocational psychology and psychological measurement and led him to understand the close relation between leisure and work experiences.

### Psychology of Leisure

Tinsley's (and his wife, Diane J. Tinsley's) theory of transcendent leisure experience provides a comprehensive explanation of the causes, attributes, and benefits of leisure experiences and a rich framework for research on leisure motivation. The Tinsleys and their associates have investigated more than 80 leisure activities and identified the psychosocial benefits derived from each. Based on this research, they developed a taxonomy that distinguishes among 11 types of

leisure activities. Their research provides the basis for counseling individuals regarding a variety of leisure-related issues. Extensive research evidence documents the validity and usefulness of this taxonomy. In recognition of his contributions to the study of leisure, Tinsley has been elected a Fellow (and President) of the international Academy of Leisure Sciences.

### **Vocational Psychology and the Person–Environment Fit Model**

Tinsley is a leading expert on the person–environment fit (P–E fit) model and its use in vocational selection and placement. John Holland’s hexagonal congruence model has been the preeminent P–E fit model of vocational choice since the late 1970s. Holland’s theory stimulated a large body of research, and initial results were interpreted as supportive of the theory. As a result, the assessment devices used in vocational choice and in classifying vocational information were modified to use the Holland system.

Tinsley challenged this view. He demonstrated that the research methods used to investigate the hexagonal congruence model were flawed and may have led to spurious conclusions. Tinsley concluded that Holland’s model fails to predict increased job satisfaction and other important vocational outcomes and questioned the validity of Holland’s model as a basis for career counseling. Tinsley’s work should stimulate the development of alternative approaches in the coming decade.

In recognition of his leadership in vocational psychology research, Tinsley was appointed editor of the *Journal of Vocational Behavior*, the leading vocational psychology journal. During his tenure as editor, he expanded the editorial board to include international scholars and pioneered the electronic submission and review of manuscripts. Under his editorship, the journal emerged as the most influential periodical in the field of vocational psychology, indicated by *Social Sciences Citation Index* data.

### **Expectations About Counseling**

Research shows that a limited number of common factors found in most therapeutic approaches are responsible for the benefit clients obtain from therapy. The two most widely acknowledged common factors are the therapeutic relationship and the client’s expectations. Tinsley is the foremost authority on expectations about counseling; his research with his wife and

associates is the most extensive program of research on expectations.

Early in the 1970s, Tinsley developed the Expectations About Counseling—Brief Form (EAC-B), a measure that has been used in over 100 empirical investigations of counseling process and outcome. The EAC-B has been translated into Chinese, French, German, Icelandic, Italian, and Spanish for use in investigations throughout Europe, Asia, and Central and South America. Tinsley’s work on the EAC-B and his research provided a clear operational distinction between expectations and preferences and eliminated a source of conceptual confusion that had troubled the discipline for decades.

Tinsley demonstrated that expectations about counseling are related to students’ level of psychosocial development; that clients having positive expectations about counseling become more interpersonally involved in counseling and discuss more personally meaningful issues beginning with the initial interview; and that unrealistic expectations interfere with success in counseling. However, individuals from different ethnic backgrounds have significantly different expectations about counseling, and they differ in their preferred working style.

### **Research Methodology**

Tinsley’s frequent contributions on statistics, research methods, and assessment have contributed greatly to the methodological sophistication of counseling psychologists. His mid-1970s paper on interrater reliability and agreement is the definitive treatment of that issue. His explanation of discriminant function analysis remains a staple for teaching graduate students this technique. His frequently cited paper on factor analysis, written with Diane J. Tinsley, is noteworthy for making this topic accessible to counseling psychology graduate students and faculty. His procedure used in “Synergistic Analysis of Structured Essays: A Large Sample Discovery Oriented Qualitative Research Approach” illustrates a creative approach to combining the methodological rigor of quantitative research with the flexibility of discovery-oriented qualitative research.

### **Professional Psychology**

Tinsley spent his professional career at SIUC with the exception of visiting appointments during sabbatical leaves and brief stints at the University of Oregon and

University of Florida. He directed the SIUC doctoral training program from 1977 to 1995, during which time the program became one of the most influential programs in counseling psychology. During his tenure, empirical studies demonstrated repeatedly that the program was among the top five in research productivity. Graduates of the SIUC program and junior faculty mentored by Tinsley have established successful careers in research, teaching, and practice and program graduates have been the recipients of APA awards for teaching and for research excellence. Tinsley's most lasting contribution to psychology may well prove to be the students and junior faculty he trained as the next generation of leaders in psychology.

## TRAINING IN ORGANIZATIONS

Training refers to activities designed to facilitate the acquisition of knowledge, skills, and attitudes relevant to performance in an occupation. Training is a major investment for many organizations, with developmental activities occurring at all levels of the organization and at various career stages. A major goal of training is often to improve organizational outcomes (e.g., efficiency, costs, turnover), but individuals engaged in these developmental opportunities also experience benefits that may extend beyond their current positions. Thus, workplace training can play an important role in individual career development.

Training activities in the workplace can range from informal exchanges among employees to formal programs developed or purchased by the organization. For example, for some jobs most of what is learned comes from informal on-the-job training, where more experienced employees take a primary role in explaining how to complete tasks. Informal training can also take the form of mentorship relationships that develop naturally rather than through formal organizational programs. On the other hand, many jobs require more formal workplace training, involving scheduled training programs or assigned mentorship roles.

Training also varies widely in terms of content and specificity. Many training programs focus on job-specific knowledge and skills. These programs are designed to teach newcomers how to perform the job or to update the knowledge and skills of more experienced employees given changes in the job. Other training programs have a broader focus and thus are more likely to result in individual capabilities that may apply across jobs. For instance, programs focusing on communication skills, diversity issues, managerial competencies, or executive development may enhance not only short-term performance, but also longer-term career development. This type of broader impact may also be seen with training programs explicitly designed to improve employee career management. These career self-management training programs are linked to an increasing trend in which organizations are taking a less central role in employee career management. The programs are intended to encourage employees to take greater responsibility for their career progression and to develop relevant behaviors such as those related to developmental feedback seeking (e.g., seeking feedback on performance) and job mobility preparedness (e.g., being proactive in identifying new career opportunities).

Training programs are more likely to be successful when developed, implemented, and evaluated using a systematic approach. Although a number of systematic approaches to training may be useful, a well-established general framework that often serves as the basis for formal employee development is the instructional systems design approach. This approach specifies an integrated set of processes for the systematic development, delivery, evaluation, and continuous improvement of instructional programs. Thus, the major components of this model consist of needs assessment, training design and delivery, and evaluation.

### **Needs Assessment**

During the needs assessment phase, training developers identify the goals and objectives of the training program. The needs assessment process should consider needs at the organization, job, and person level. At the organization level, short- and long-term goals should be examined along with management expectations and support for the training initiative. Without support from top management, it may be difficult to obtain the resources required to develop and implement an effective training program. At the job level, needs assessment involves identifying the jobs targeted for training and specifying the knowledge, skills, and attitudes required to perform the essential functions of these jobs. Various job analysis methods may be applied at this step. At the person level, individuals are assessed in terms of how well they perform essential job functions and where they stand on the required capabilities underlying task performance established in the job analysis. This individual-level assessment is primarily intended to identify those most likely to benefit from training. The needs assessment phase results in the specification of instructional objectives that serve as input to both training program design and later evaluation of the program.

### **Training Design and Delivery**

After determining objectives of the training program and identifying those individuals who would likely benefit from participating, issues of training design and delivery must be considered. This phase involves examining training methods, media, and learning principles in light of needs assessment outcomes. Numerous training methods may be considered, including one-on-one instruction, lectures, audio-visual

presentations (e.g., videotapes), role-playing, simulations, and on-the-job training. The use of computers and Web-based approaches in training continues to grow as the availability, flexibility, and familiarity with computers increase and the costs of these applications decline. Computer-driven training programs offer standardized administration and in many cases may capture various performance criteria automatically and in real time. Regardless of method, training should be administered in an environment conducive to learning. For example, if training is delivered by an individual (e.g., through lectures), he or she should be organized, knowledgeable, patient, and respectful. At this stage it is again important to consider the individuals receiving the training; one method may be clearly superior given the nature of the material to be learned and the individuals learning it.

Efforts should also be made to integrate well-supported learning principles into the training program. Such principles include the provision of feedback, overlearning, and producing the actual response or behavior. Additional considerations include whether training should be conducted in a single session or divided into several sessions over time (i.e., massed vs. spaced) and whether tasks should be trained as whole units or broken down into simpler parts (i.e., whole vs. part).

### **Evaluation**

Following training design and delivery, program evaluation is essential for examining the extent to which training objectives are being met. Evaluation can come in many forms, from multiple sources, and at various times. However, the process of evaluation generally requires specifying appropriate evaluation criteria given training objectives, designing an approach to collecting data relevant to these criteria, collecting data, and analyzing and interpreting these data.

Several models of training evaluation have been proposed. One popular approach to evaluation includes the assessment of trainee reactions, learning, behavior, and results. Trainee reactions refers to how well participants liked the training program and may involve assessment of affective reactions (i.e., enjoyment) and utility perceptions (i.e., perceptions of usefulness). Learning refers to the knowledge and skills trainees have acquired and is often measured with posttraining performance or paper and pencil assessments. Behavior refers to on-the-job performance and

might be measured with job performance ratings or work samples. Finally, results refer to broader organizational outcomes linked to training (e.g., efficiency gains, cost reduction, sales growth).

Another well-established model of evaluation includes the assessment of cognitive, skill-based, and affective learning outcomes. For cognitive outcomes, the criteria of interest pertain to verbal knowledge (e.g., assessed through multiple-choice exams), knowledge organization (e.g., assessed through judgments of similarity among core concepts), and cognitive strategies (e.g., assessed through measures of metacognitive skills). For skill-based outcomes, the focus is on skill compilation and automaticity, which is characterized by faster and more fluid performance as well as a decrease in the attentional resources required for task performance. For affective outcomes, criteria include attitudes and motivational tendencies such as trainee self-efficacy and goals.

Following evaluation, the training program may be revised to address any deficiencies discovered. Ideally, training should be continuously evaluated and improved, with evaluation results feeding back into needs assessment and influencing subsequent training design and delivery decisions.

## TRAIT-FACTOR COUNSELING

---

Trait-factor counseling approaches assume that career choice may be facilitated and career outcomes optimized through a fairly straightforward process of matching an individual's most relevant work-relevant characteristics (abilities, interests, values, etc.) with information regarding job activities, demands, rewards, and availability. The counseling process for this approach typically starts with a client interview, then proceeds to extensive psychometric assessment of the client's work-relevant characteristics, and is finalized with an interpretation of assessment results with connections being drawn between these results and one or more occupational classification systems. Trait-factor counseling assumes that having been provided with accurate information about self and jobs, most individuals will be able to make a rational choice of career.

### History

Conceptually, the origins of trait-factor approaches to career counseling can be traced to Frank Parsons's pioneering efforts to better match individuals with jobs. This matching process involved using an accurate understanding of an individual's work-relevant attributes (skills, aptitudes, interests, etc.) and a thorough knowledge of both jobs and the employment market to optimize job choice. Parsons proposed that once self-knowledge was coupled with knowledge about jobs, a rational decision could be made regarding the best match between the two for a given individual. One of the greatest challenges to this approach, then and now, involves how to best define individuals and jobs.

It was not until the 1930s that statistical applications and psychometric methods had advanced to the point that the matching dimensions could be empirically derived and quantitatively evaluated. The Minnesota Employment Stabilization Research Institute

was established at the University of Minnesota to assist workers who had lost their jobs due to the Great Depression. The Minnesota researchers operationalized Parsons's basic concepts using the research methods of differential psychology to develop psychometric instrumentation and occupational classification systems. During this decade, Edmund G. Williamson was appointed director of the University of Minnesota Testing Bureau (now the University of Minnesota Counseling and Consulting Center). Williamson successfully adapted the methods developed by the Minnesota Employment Stabilization Research Institute to address the career development concerns of college students. Williamson wrote so prolifically and influentially on this approach that it is sometimes referred to as the Minnesota point of view.

Within a decade, the methods and technologies developed at Minnesota were applied to the monumental task of classifying armed forces recruits and assigning them to appropriate positions as the U.S. military rapidly expanded during World War II. Following the war, these approaches were adopted by both vocational rehabilitation counselors in the Veterans Affairs Medical Centers and by college counselors struggling to cope with the influx of returning veterans needing assistance with their transition to civilian employment. It is not coincidental that John Holland, whose theory of vocational personalities and work environments is the most widely used trait-factor model, spent his war years conducting military classifications and later become a University of Minnesota graduate. It is also not coincidental that another very influential trait-factor approach, the theory of work adjustment, was also the product of University of Minnesota researchers.

### Criticisms

Trait-factor counseling has been widely criticized on a number of fronts. Its harshest critics have labeled trait and factor counseling as "test and tell" and "three sessions and a cloud of dust." Because assessment and interpretation require high levels of counselor expertise and input, the knowledge and power differential between counselor and client tends to be highlighted. This has led some to argue that trait-factor approaches are too prescriptive and too directive. A fundamental assumption of trait-factor models is that given good information, individuals will make good (or rational) decisions. Consequently, much of the counseling

effort is aimed at providing clients with objective information about self and jobs. In response, critics have charged that trait-factor approaches place undue emphasis on testing, that they ignore counseling processes and represent techniques rather than theory. Another major criticism of trait-factor counseling takes aim at the foundational assumption that given good information, individuals will make rational decisions. These critics argue that in addition to factual information, decisions are also influenced by factors such as affective considerations, one's personal history, and the opinions of significant others.

### Legacy

Despite the criticisms discussed above, trait-factor counseling has been and continues to be widely influential. In part this is due to the scientific rigor that was devoted to developing both instrumentation and occupational classification systems. Many of the assessment devices (e.g., Minnesota Importance Questionnaire and Strong Interest Inventory) developed within this framework continue to enjoy widespread usage. Initially, advances in psychometrics allowed the development of instruments to operationalize trait-factor concepts. However, these successes spurred further advances and psychometrics as a field benefited greatly from the testing focus of trait-factor approaches. For example, the empirical keying methodology pioneered by E. K. Strong for the Strong Interest Inventory and its success in differentiating between discrete occupational groups directly inspired and influenced the subsequent development of the Minnesota Multiphasic Personality Inventory, which uses empirical keying to differentiate between normals and those having psychiatric diagnoses.

Also contributing to the ongoing influence of trait-factor models is that even at the end of a thoughtful and thought-provoking career counseling process, there is often still a need for well validated, objective information about how well one could expect to fit into those occupations that are of most interest. Person-environment fit models, such as Holland's theory of vocational personalities and work environments and the theory of work adjustment, represent the evolution of trait-factor counseling from its relatively atheoretical roots to mature and dynamic theories of career choice and adjustment. Although both models have great depth and sophistication, their most basic concepts can easily be explained to clients. Both

benefit by retaining the intuitive, commonsensical appeal of Parsons's original notion that the more similar the gifts and needs of an individual are to the requirements and rewards a job has to offer, the better the outcome. It can be argued that the Occupational Information Network (O\*NET) represents the current pinnacle of trait-factor counseling approaches. From a theoretical perspective, the O\*NET's model clearly draws upon Holland's theory of vocational personalities and work environments and the theory of work adjustment. The O\*NET also represents fulfillment of Frank Parsons's goal of making vocational guidance available to the masses, as its online resources (including tools for self-assessment and a database of occupational information that is periodically updated) are open to all.

## TRANSITION BEHAVIOR SCALE

---

The Transition Behavior Scale, Second Edition (TBS-2) has as its intention the identification of behaviors that are thought to interfere with successful societal transition and employment from high school to adult life for special needs students. There are two versions of the TBS-2: a self-report instrument (to be completed by the student) and a school instrument (the identified

student is rated by school personnel who can reasonably observe the student). Each of the versions has subscales to identify work-related skills, interpersonal relations, and social–community expectations. The scales are accompanied by a manual to provide goals, objectives, and interventions for an array of behaviors that may limit successful independent living and work adjustment.

### Reliability and Validity

Each scale is accompanied by a technical manual providing a concise literature review and sections on item development, sampling, reliability, validity, and administration. The technical information is reasonably comprehensive and subscribes to all psychometric standards of instrument development. The samples (over 2,500 students) upon which the data are based appear to be diverse in terms of gender, ethnicity, socioeconomic status, and geography. The students in the sample were randomly selected at the selected school sites and site personnel were given specific instructions not to exclude any student. Measures of reliability include internal consistency, test–retest, and interrater (for the school version). Examples of construct validity (factor analyses), content validity, and criterion related validity were all demonstrated appropriately. Administration guidelines are included.

### Interpretation

Each manual has a brief chapter regarding interpretation. The chapter provides information on scoring each scale's meaning, conversion to a standard score, and developing a scale profile. As well, the chapter suggests that any score more than one standard deviation below a normative mean that is provided indicates that intervention may need to occur. This conclusion and the interventions suggested are based on the literature and assumptions that being below the norm of a group of selected students might require an individualized education plan (IEP).

### Caveat

The TBS-2 as a scale is well supported through the literature. The technical qualities of the scales are generally sound and presented clearly by the authors. The scales to be administered to students directly or used to rate students by site personnel appear to be easy to

use. The IEP and intervention manual are comprehensive and complete with over 200 pages of goals, objectives, and direct interventions.

With the above in mind, one caveat needs to be stressed. As with any measure that leads to recommended intervention, outcomes of that intervention in terms of eventual success go to the validity of the measure itself. Thus, with the TBS-2 a student who scores or is rated one standard deviation below some normative mean is said to need skills to ensure transition or job success. Although the recommended intervention is rational and has a basis in the literature, no direct evidence of success is provided.

## UNEMPLOYMENT

---

*See* JOB LOSS

---

## UNISEX EDITION OF THE ACT INTEREST INVENTORY

---

The Unisex Edition of the ACT Interest Inventory (UNIACT) is an assessment designed to identify personally relevant career (educational and occupational) options. Results are intended to help people see the connection between the work world and the activities they like to do. UNIACT is a component of several programs and services offered by ACT, such as the ACT Program, PLAN, EXPLORE, DISCOVER, and the Career Planning Survey. Through these programs and others, UNIACT is administered to about 4 million persons annually. Since 1973, the ACT Interest Inventory has been administered to about 70 million persons, making it one of the most used psychological assessments in the world.

### Instrument Characteristics

#### *Items*

UNIACT items emphasize work-relevant activities (e.g., build a picture frame, conduct a meeting, help settle an argument between friends) that are familiar to persons, either through participation or observation. Item content does not include occupational titles

or specific job duties because persons needing help with career planning may have minimal or inaccurate knowledge about a wide range of occupations. Items are responded to using a three-choice response format (*dislike, indifferent, like*).

UNIACT items were carefully chosen to minimize gender-related differences in responses. Item content avoids activities subject to gender-role stereotypes. This feature of UNIACT minimizes gender divergences in the career options typically suggested to males and females and permits the use of combined-sex norms.

#### *Scales*

UNIACT results are reported for six scales paralleling the six interest and occupational types in John L. Holland's theory of careers. Scale titles and descriptions (with parallel Holland types in parentheses) are listed as follows:

*Science & Technology* (Investigative): Investigating and attempting to understand phenomena in the natural sciences through reading, research, and discussion.

*Arts* (Artistic): Expressing oneself through activities such as painting, designing, singing, dancing, and writing; artistic appreciation of such activities (e.g., listening to music, reading literature).

*Social Service* (Social): Helping, enlightening, or serving others through activities such as teaching, counseling, working in service-oriented organizations, engaging in social-political studies.

*Administration & Sales* (Enterprising): Persuading, influencing, directing, or motivating others through

activities such as sales, supervision, and aspects of business management.

*Business Operations* (Conventional): Developing and/or maintaining accurate and orderly files, records, accounts, and so on; designing and/or following systematic procedures for performing business activities.

*Technical* (Realistic): Working with tools, instruments, and mechanical or electrical equipment. Activities include designing, building, repairing machinery, and raising crops/animals.

## Background

### History

The ACT Interest Inventory was first introduced in 1973. The UNIACT edition of the ACT Interest Inventory was introduced in 1977. Two major revisions of UNIACT, based on both item content considerations and empirical evidence of item performance, were undertaken in 1987–1989 and 2003–2006, leading to the current 90-item and 72-item versions of the inventory. The current versions are available in two levels: Level 1 is intended for students in Grades 8–12, and Level 2 is intended for college students and adults.

### Underlying Theory

According to Holland's theory, relationships among Holland's six types can be represented by a hexagon. Types adjacent on the hexagon (e.g., Social and Artistic) resemble each other most, while types on opposite sides of the hexagon (e.g., Social and Realistic) resemble each other least. Holland's hexagon is a two-dimensional figure, thus suggesting that there are two underlying dimensions.

Numerous studies suggest that two bipolar dimensions of work tasks and work-task preferences underlie Holland's hexagon: data versus ideas, and things versus people. The relationships between these four basic work tasks and the six UNIACT scales are listed as follows:

*Science & Technology*: Work typically involves primarily *ideas*, and secondarily, *things*.

*Arts*: Work typically involves primarily *ideas*, and secondarily, *people*.

*Social Service*: Work typically involves primarily *people*.

*Administration & Sales*: Work typically involves primarily *data*, and secondarily, *people*.

*Business Operations*: Work typically involves primarily *data*, and secondarily, *things*.

*Technical*: Work typically involves primarily *things*.

## Visual Interpretation

One of the special features of UNIACT is that results are presented visually via the ACT World-of-Work Map. This map locates and displays occupational groups on two dimensions according to their involvement with data–ideas and people–things. Based on empirical data from multiple sources, the map provides an overview of the entire world of work, summarizing a large amount of information to facilitate the understanding of basic similarities and differences among occupations.

Because the data–ideas and people–things dimensions underlie Holland's six types, scores on Holland's six types can be expressed as a location on these dimensions—and hence, on the World-of-Work Map. UNIACT scores are transformed to map locations, letting persons see the direction of their work task preferences and identify occupational options having related work tasks. For example, if a person's highest UNIACT scores suggest an interest in working with people, results refer the person to the areas of the map with occupations that primarily involve working with people. In effect, the World-of-Work Map serves as a visual bridge from scores to occupations. The map can be used to link Holland-type scores from any career assessment to occupational options.

## Technical Information

### Norms

Nationally representative norms are based on persons at four age levels: Grade 8, Grade 10, Grade 12, and adult. All norms were obtained from ACT program files. To improve the national representativeness of the samples, individual records were weighted to more closely match the characteristics of the target populations with respect to gender, ethnicity, and region of the country. Samples consisted of more than

250,000 students for the Grade 8–12 levels and more than 2,000 persons for the adult level.

### Reliability

Evidence of reliability and validity is essential in evaluating any psychological assessment. One type of reliability is *internal consistency*—the degree to which the items in a scale are related to each other. For example, internal consistency reliabilities for a large sample of Grade 12 students who completed the 72-item UNIACT ranged from .85 to .91 for males and from .83 to .91 for females. Results were similar for a large sample of Grade 8 students: .82 to .90 for males and .81 to .89 for females.

Judgments about the adequacy of reliability and validity evidence for an assessment should be made in context. Factors such as the purpose of the assessment and the number of items in the scale should be kept in mind.

### Validity

Validity generally refers to the extent to which assessment results measure what they are purported to measure. Thus, validity is evaluated in light of the purpose of the assessment. As mentioned above, UNIACT results are used to identify occupations in line with a person's preferences for basic work tasks. If UNIACT results differentiate various criterion groups—and do so in sensible, meaningful ways—they can be used to identify occupational groups having work tasks that are compatible with a person's preferences.

Evidence of criterion-related validity requires data from criterion groups. Typical methods of determining criterion group membership involve selecting high school seniors with the same occupational choice, college students with the same major, or employed adults with the same occupation. According to Holland's theory, I-type (scientific) interests should predominate among I-type criterion groups, A-type (artistic) interests should predominate among A-type criterion groups, and so on. Across a number of groups, agreement between criterion group membership and measured predominant interests (highest interest score) provides an index of criterion-related validity.

Based on data collected since 1973, using both current and prior editions of UNIACT, agreement rates

(expressed as the percentage of groups with matching predominant interests) were obtained for more than 600 groups representing more than 78,000 persons. The total agreement rate across all groups was 73%. Agreement rates varied by age: 72% for high school seniors, 70% for college students, and 81% for employed adults. These agreement rates far exceed chance (1 in 6, or 17%).

The above evidence represents only a small part of the extensive reliability and validity evidence available on UNIACT. Additional information, based on data from various age groups and racial/ethnic groups, is found in published studies and summarized in manuals and other materials available from ACT. For example, the UNIACT technical manual summarizes reliability and validity evidence for five racial/ethnic groups.

---

## VALUES SCALE

---

The Values Scale (VS) is used to assess values in life roles, largely in relation to work. Items query both values desired in life roles and the place of work in value manifestation. The VS can be used in career counseling to identify areas of values conflict and deficits in career development and to connect values with the career planning process. The VS provides 21 values scores: ability utilization, achievement, advancement, aesthetics, altruism, authority, autonomy, creativity, economic rewards, lifestyle, personal development, physical activity, prestige, risk, social interaction, social relations, variety, working conditions, cultural identity, physical prowess, and economic security. The 21 values can be reported in five subsets: inner-oriented, group-oriented, material, physical prowess, and physical activity. Values assessed are both intrinsic (e.g., creativity, ability utilization) and extrinsic (e.g., economic rewards, security). The VS is intended for use with junior high school students to adults as a tool for research, career commitment evaluation, and individual career counseling. The 2-page, 106-item VS can be group or individually administered in 30–45 minutes and profiles compared to U.S. norms. Responses are captured on a 4-point scale (*little or no importance* to *very important*). The VS can be hand-scored or sent to the publisher for scoring. An individual report is provided in an easily readable profile format.

The VS manual lists internal consistency reliabilities for individual scales in the .6 to .8 range and stability reliabilities from .5 to .8. Support for validity is

claimed from content review during scale development, by structural (factor) analysis, and known-group comparisons (e.g., gender, age differences). Further general support for the validity of the VS has been found by other investigators. There is also research support for use of the VS in career counseling.

The VS was initially developed by an international panel for use in cross-national research. The project's intent was to produce a global knowledge base useful in developmental career counseling. Donald Super, a prominent theorist in the area of career development, was a coordinator of the Work Importance Study, which included research teams of vocational psychologists worldwide. Each national team contributed to the project via literature reviews, providing or revising construct definitions, and writing or reviewing and revising items that led to creation of the VS.

---

## VOCATIONAL IDENTITY

---

Vocational identity and career identity are related, but vocational identity as a concept extends beyond career identity. Career identity is indicative of the current career being pursued, whereas vocational identity represents an identity related to work over a long term and is more stable as one develops and becomes more confident in his or her career aspirations. Vocational identity reflects a stable pattern of interests, goals, abilities, and talents. These aspirations, interests, and goals in short provide a good framework of the work and career histories in individuals. So a person with a strong vocational identity would have a clear sense and/or picture of his or her goals, interests, skills, suitable occupational choices, and confidence in making career decisions. Strong vocational identity also refers to the ability to display confidence in the event of unforeseen and ambiguous career-related problems that may arise. Vocational identity can be conceptualized on three main domains. The first is the structural domain, which refers to how the individual negotiates the world of work and could include cognitive factors. The second domain involves relations (social and emotional) and the third attempts to describe behaviors and experiences in which vocational identity is involved. Therefore, vocational identity can be viewed as a complex, multidimensional, and developmental construct.

### Formation of Vocational Identity

Vocational identity is an integral part of human functioning and human development. This is because one of the principal tasks in human development, especially for adolescents, is the formation of various identities. One of these identities includes that which is related to career exploration. This process includes

the formation of career objectives, career goals, career aspirations, and career plans. Regardless of ethnicity, socioeconomic status, education, or age, career is an important aspect of this identity formation.

Vocational identity formation is a pivotal juncture in our lives as it symbolizes the point where we attempt to actualize our emerging self-concepts while integrating our past and present aspects of ourselves in the arena of work and careers. Clearly, vocational identity is an integral part of our functioning in the world of work. Vocational identity is a dynamic construct as it has a developmental quality about it. Vocational identity can be stable for some individuals, but usually it changes for most individuals depending upon factors such as age, experience, career training, occupational development, and stronger ego-strength. Vocational identity is a multidimensional, complex, and developmental construct that captures career and vocations more accurately than other work-related constructs, and therefore, it needs to be further explored and expanded.

### Career Development and Satisfaction

The concept of vocational identity has been linked to the process of career development. However, many authors have also mentioned that there is a gap in the literature and research on vocational identity; therefore, its usefulness has been questioned and has yet to be empirically verified. It is important to establish a relationship between vocational identity and career development for adolescents and early adults as these are the phases when the issues of identity and career are both salient and interrelated.

According to prominent researchers in the field of vocational and career psychology, vocational identity is a better prediction of job satisfaction than investigating the congruence of interests and the environment. Hence, it has been suggested that concepts such as career beliefs, interests and goals be incorporated as a more accurate method of measuring career stability and career changes. A person with a strong vocational identity is more likely to find jobs/occupations that are congruent with his or her personal characteristics and personality in addition to being congruent with a particular work environment. On the other hand, a weak vocational identity would suggest that a person is more likely to make incompatible choices, make frequent job transitions, and transition through a wide set of successive occupations. This

weakness does not bode well for both the well-being of the individual or for the greater good of society in terms of dollar amounts, time, and efforts invested that end up being unfruitful and frustrating. Therefore, these consequences suggest that a vocational identity scale would be both useful in helping individuals find jobs that they are successful at and that make them happy.

### Vocational Identity Scale

John Holland developed a vocational identity scale as part of My Vocational Situation in 1980, nearly 30 years ago. Since then there has not been much development in this area. Most researchers and practitioners have stayed with using Holland's scale. Holland's scale measures constructs on a number of domains, including vocational attitudes, vocational commitment, desirable career beliefs, desirable problem-solving attitudes, and rational career decision-making styles. Items are measured using *true* and *false* statements, and sample items include "I need reassurance that I have made the right choice of occupation" and "I am concerned that my present interests may change over the years."

Holland's scale does have some positive correlations to other scales such as the Career Decision Scale and the Medical Career Development Inventory, but none of the scales came out being superior, including Holland's Vocational Identity Scale. Attempts have been made to demonstrate some of the psychometric properties of Holland's Vocational Identity Scale. For instance, research indicates that the scale has a retest reliability of .75 at about 1 to 3 months' time interval. In addition, the scale has substantial construct and convergent validity and modest discriminant validity. For instance, there has been overlap identified between the Vocational Identity Scale and career maturity ( $r = 0.69$ , 48% of shared variance). Overall, the scale appears to demonstrate some good psychometric properties; however, researchers have concluded that the scale needs further validation in practical settings. Some criticism of the Vocational Identity Scale include that the scale fails to measure the complex, multidimensional nature of the vocational identity construct. For instance, it fails to encompass the personal, social, and emotional dimensions of vocational identity. In addition, the current scale does not capture the developmental nature of vocational identity and it has not been updated since it was developed.

### Future Directions

A stable-strong vocational identity is related to a smaller number of career aspirations as one begins to narrow down the number of occupational goals he or she has. This is because a person with a high-strong vocational identity will have more confidence in his or her career decision-making processes and so will have more satisfaction and contentment related to his or her career aspirations and goals. There are other aspects that are still unknown about the construct of vocational identity. For instance, based upon its definition it could be assumed that vocational identity is related to constructs such as occupational commitment, clarity, and/or stability, but its relationship to phenomenon such as the differentiation of occupational interests still has to be investigated. Clearly, more expansion and investigation with this construct needs to be done in order to get a better understanding and in order to meet the career satisfaction and occupational goals of individuals.

## WALSH, W. BRUCE (1936– )

---

W. Bruce Walsh is one of the leading researchers and writers in the field of vocational psychology. Walsh was born into a family deeply committed to education. He is one of 11 members of his family to attend Pennsylvania State University. Walsh graduated from there with a B.S. degree in Economics from the Smeal College of Business Administration. It is perhaps his training as an economist that helped to develop his research interest in person–environment human behavior. Walsh, however, never worked as an economist. After completing his undergraduate degree, he went directly to Kent State University where he studied sociology and worked in residence halls coordinating programs and advising students.

Walsh continued his work with students as he pursued his doctorate at the University of Iowa. While he worked on the Ph.D. in Counseling and Vocational Psychology he continued his work with college students by advising the fraternity council and conducting academic counseling. It was during his career at the university that Walsh began to foment his identity as a psychologist with his placement as a junior counselor and intern at the Iowa University counseling center. His life also became cemented to vocational psychology as he worked with his major advisor, John Holland.

### Early Research

Walsh's long publishing career began with studies around his work with residence halls and academic

advising. His early research seemed to forecast his later dedication to research on person–environment theories of human behavior in that his very first publication was titled “College Student Residence and Academic Achievement.” At about the same time, Walsh investigated the validity of self-report data. In many ways, the self-report research is seminal because so many researchers then and now use self-report as a primary assessment tool. Walsh's research demonstrated that self-report data are accurate and valid. Although doubt continues to linger about self-report data, Walsh's work was the first systematic inquiry into this assessment methodology and does provide some reassurance to the thousands of researchers who use self-report. Though individuals who know Walsh well remember the self-report studies, most students of psychology will recall Walsh for his person–environment work.

While at the University of Iowa Walsh began his decades-long association with person–environment research. It was perhaps Walsh's early training as an economist and later research with college students that eventually led him to the study of the influence of the environment on the behavior of people and the influence of human behavior on the environment. He published one of his seminal works, *Theories of Person-Environment Interaction*. From there, Walsh conducted numerous person–environment studies and initiated the person–environment book series. Many of the investigations of John Holland's theories are directly attributable to Walsh and his numerous graduate students. With about two dozen articles on Holland's theories, Walsh invigorated the study of this vocational theory as well as inspired the study of other theories.

## Vocational Psychology

Walsh moved from a study of Holland's theory to present a broader view of the specialty of vocational psychology. Walsh's work has helped to shape a complete picture of Vocational Psychology. Walsh pulled together the leading researchers and writers in this field for his various handbook series. He began his initial work with the two-volume set of *Handbook of Vocational Psychology* with Samuel Osipow in 1983 and added four other handbooks that included as coeditor Mark Savickas for the 2005 edition of the *Handbook of Vocational Psychology* and Mary Heppner for the *Handbook of Career Counseling for Women*. Walsh also focused much of his vocational psychology research and publications on African Americans and fostered his colleagues' writings on other racial/ethnic minorities and various economic classes. Because Walsh believed in exploring the entire range of variables in the study of the discipline, he and his colleagues essentially codified the specialty of vocational psychology. Walsh further stimulated the field of vocational psychology through his work in the Society of Counseling Psychology, a division of the American Psychological Association (APA). There Walsh helped found the Society for Vocational Psychology, a section of the Society of Counseling Psychology. Through the Society for Vocational Psychology, Walsh and his colleagues initiated a biennial conference on vocational psychology. The inaugural conference was hosted by Walsh in Columbus, Ohio, home of Ohio State University where Walsh served as a professor for 37 years. True to Walsh's commitment to include the entire range of elements in any profession, the Society for Vocational Psychology held its first international vocational psychology conference in Portugal in 2003.

Although Walsh is one of the primary invigorators and codifiers of the specialty of vocational psychology, his interests and his impact on the field of psychology is much broader. Walsh could easily be called a measurement psychologist. After all, much of his work on Holland's theory included validation studies of the Vocational Preference Inventory and the Self-Directed Search. But his wider work reviewed the entire field of psychological tests and assessments. He coauthored four volumes of tests and assessment books that discussed assessment of personality, cognitive ability, interests and career development, and person–environment. These books are written so that

lay persons, scientists, and practitioners can have access to material that is sometimes considered out of reach because of its perceived difficulty.

## Counseling and Counseling Intervention

Walsh has also been an active author on the subject of the entire field of counseling and counseling intervention methods. He regularly published overviews of counseling, counseling interactions, and counseling methods. In addition, Walsh has provided historical perspectives on the work of counseling psychology as the early adopters of positive psychology. And he has pushed counseling psychologists to be visionaries regarding the future of counseling psychology. He served as President of the Society of Counseling Psychology, Division 17 of the APA in 1998. During his tenure and shortly thereafter, he established a foundation for research in counseling psychology within the American Psychological Foundation and established the Division 17 Past Presidents Council in order to retain the heritage of the division and to push the further development of the field.

## Enduring Legacy

Walsh's most enduring legacy to the field of counseling psychology in general and to vocational psychology in particular is the result of work with legions of graduate students and their subsequent work with their own graduate students. Walsh's students can be found in professorships in higher education, as higher education administrators and practitioners, and organizational and corporate positions as well as in the private practice of psychology. From all of these quarters, numbers of these former students now write in the vocational psychology arena and thus ensure the vibrancy and dynamism of the discipline. For his stellar work, Walsh was honored with Fellowship status in the Division of Counseling Psychology and in the Association for Psychological Science.

Although Walsh is constantly sought after for his sage counsel in numerous areas, including as a book reviewer on topics from "Student Personnel Work in Urban Colleges" to "Measuring Ego Development," his most profound and consistent work is with person–environment behavior. In order to encourage the research and study of careers, vocational psychology,

and environment Walsh founded and edited the *Journal of Career Assessment* in 1991. From its inception through 2007, the journal has steadily grown in prominence. In 2006, the *Journal of Career Assessment* had a citation impact factor of 1.211. In addition, Walsh extended his sphere of influence beyond counseling psychology to a diverse group of colleagues who were working on his early and sustained research interest in human behavior and environments. He became active with Division 34 of the APA, Population and Environmental Psychology, and became the representative to the APA governing council, the Council of Representatives, on behalf of Division 34. Walsh's service on the Council from 2002 to 2008 meant that he was involved in formulating policy and in helping to set direction for the entire field of psychology. His influence on the field of psychology is also reflected in his service as founding editor, acting editor, editorial board member, and/or editorial consultant on 11 major psychological journals. Walsh has published over 150 articles, book chapters, and books and has presented at major conventions nearly 100 times. His articles have appeared in leading academic journals, including the *American Psychologist*, the *Journal of Counseling Psychologist*, the *Journal of Vocational Psychology*, *The Counseling Psychologist*, *Contemporary Psychology*, and the *Journal of College Student Personnel*. His lifetime of sustained and valuable contributions was acknowledged when he received the Leona Tyler Award in 2004. The Leona Tyler Award is the highest recognition given by the Society of Counseling Psychology.

Walsh lives with his wife, Jane, in Columbus, Ohio. He retired from his 37-year career as a professor of psychology in 2002. He remains actively engaged with the psychology department in his role as Professor Emeritus at Ohio State University, and he serves as Executive Director of the W. B. W. Consulting Firm.

## WILLIAMSON, EDMUND GRIFFITH (1900–1979)

---

Edmund Griffith Williamson was born on August 14, 1900, in Rossville, Illinois. In 1925, he received a B.A. degree from the University of Illinois. He received a Ph.D. in psychology from the University of Minnesota in 1931. Williamson joined the faculty at the University of Minnesota in 1931 as assistant professor of psychology and was named director of the University of Minnesota Testing Bureau (now the University of Minnesota Counseling and Consulting Center), 1931–1938. During this decade, the Minnesota Employment Stabilization Research Institute was established at the University of Minnesota to assist workers who had lost their jobs during the Great Depression. This effort operationalized Frank Parsons's

concepts of matching the characteristics of workers with jobs using the methods of differential psychology. This approach came to be labeled *trait-factor counseling*. Williamson successfully adapted the methods developed by the Minnesota Employment Stabilization Research Institute to address the career development concerns of college students. Because of Williamson's prolific and influential writings on trait-factor counseling, it was sometimes referred to as the Minnesota point of view. Under Williamson's leadership, the University of Minnesota Testing Bureau became the prototype for all future college counseling centers.

Williamson became the coordinator of student personnel services in 1938 and was promoted to Professor of Psychology and Dean of Students in 1941. During his tenure as dean, he developed the idea of *in loco parentis*—the concept that universities should assume parental responsibility for the behavior of undergraduate students. This concept fell into disfavor in the 1960s, but is now being revisited by some universities. Contrary to the paternalism he was sometimes charged with, Williamson supported the inclusion of students' ideas and opinions in the administration of the University of Minnesota. During his career, Williamson influenced the work of many other researchers in vocational psychology. His influence was particularly strong at the University of Minnesota, which produced leading vocational psychology researchers such as John Holland, Lloyd Lofquist, René Dawis, David Campbell, and Jo-Ida Hanson during his tenure there.

Williamson retired from the University of Minnesota in 1969 and was named a regents professor emeritus. In 1977, a new building housing the University of Minnesota bookstore and student services offices was named for Williamson. Among his other career accomplishments, Williamson was a Fulbright Scholar in Japan in 1956. He served the Advisory Committee on Counseling in Vocational Rehabilitation and Education of the Veterans Administration from 1946–1969 and in leadership positions with the American College Personnel Association from 1941–1954, including serving as president in 1944–1945. He died on January 30, 1979. Williamson's leadership in the field of student counseling and his scholarly accomplishments were such that many consider him the leading figure in the founding of the field of counseling psychology.

## WORK-BOUND YOUTH

---

The majority of youth enter the world of work prior to receiving postsecondary education or training. By age 26, 85% of youth receive a high school diploma; however, only 27% receive a 4-year college degree. The economic consequences of being in the world of work without a college degree in the United States are staggering. The U.S. Federal Reserve reported that the median income level for individuals without a high school degree was \$17,000 per year, \$34,000 for individuals with a high school degree, and \$41,000 for individuals with some college experience.

Renewed efforts must be made to establish optimal learning environments within school and community settings that effectively prepare all youth to make successful transitions into the world of work. Fortunately, the Secretary's Commission on Achieving Necessary Skills (SCANS) has provided an excellent outline of necessary work readiness skills and dispositions. SCANS identifies a set of five competencies considered to be hallmarks of expert workers, and a three-part foundation of personal qualities and skills considered essential for success in the workplace. The five competencies include the ability to effectively use resources, interpersonal skills, information, systems, and technology. The three foundation skills and qualities include basic skills (such as reading, writing, mathematics, listening, and speaking), thinking skills (such as thinking creatively, making decisions, and solving problems), and personal skills (such as displaying responsibility, self-esteem, sociability, self-management, and integrity).

With this foundation of essential work skills and dispositions, the counseling profession can facilitate the ability of youth to successfully enter the world of work by helping schools and youth-serving community settings establish optimal learning environments.

One of the first models of career development, Parsons's traditional person–environment fit model, argued that individuals and occupations possess relatively stable characteristics, and the goal of career counseling is to establish a match between personal characteristics and occupations that rely on those characteristics. Recent theory and research in developmental psychology and changes in the world of work have cast doubt on the utility of traditional person–environment fit strategies as the only means of establishing work readiness. An alternative perspective is that individuals possess modifiable dispositions, rather than stable trait characteristics. According to Lerner's developmental contextualism, youth are embedded within environments that facilitate or impede their development. For example, the quality of teachers in the classroom influences the development of youth literacy and numeracy skills. It is assumed in this perspective that the vast majority of lower-income youth, urban youth, and youth of color possess the ability to read and perform mathematical operations. Thus, the large achievement gap between these populations and higher income and predominately White youth are accounted for by differences in the quality of learning environments, not ability levels. Establishing optimal learning environments allows youth of all ages to move toward achieving their true potential.

The SCANS skills and dispositions include both cognitive and affective developmental domains. Cognitive development involves traditional academic outcomes such as literacy and numeracy, whereas affective development involves motivation and confidence. Counselors can support educators by helping students become invested in using learning opportunities to develop the range of skills and dispositions needed to achieve their career goals. Counseling as a discipline can help establish optimal conditions for developing work readiness skills and dispositions by focusing attention on the affective development areas necessary for success in school and work, such as motivation, confidence, and social connections.

Motivation is perhaps best described by Deci and Ryan's self-determination theory, which articulates strategies to help youth engage in activities because they find them meaningful and enjoyable rather than because they feel forced to do them or fear letting others down. Performing an activity because it is perceived as meaningful and enjoyable is referred to as internally based motivation while performing an activity because one feels forced to or in order to avoid letting others down is referred to as

externally based motivation. Deci and Ryan argue that optimal learning environments are those that establish strong relational bonds between youth, peers, and adults. These environments are optimal because individuals develop meaning and enjoyment in activities in which they experience a sense of social connectedness or belonging. Therefore, youth are more likely to be motivated to attend school when they feel connected to teachers and peers. An example of interventions based on a counseling perspective designed to improve relational connections is the Hear My Story curriculum developed by Howard and Solberg. The Hear My Story curriculum involves working with a language arts teacher who provides literature and autobiographical writing lessons. The counselor joins in the activity by explaining to the class that everyone will be encouraged to read their writing sample to the class and that the counselor and teacher will be sharing their stories as well. The counselor also establishes the rules for creating a safe sharing environment. By sharing their stories, students and teachers learn about the diverse life experiences that are occurring among and between peers and adults.

Other important areas of affective development are highlighted in Bandura's social cognitive theory, which argues that optimal learning environments include four sources of self-efficacy. Self-efficacy refers to one's confidence in one's ability to successfully perform an activity. The four sources of self-efficacy include mastery experiences, vicarious (role modeling) experiences, verbal persuasion, and anxiety management. Mastery experiences are those that involve successfully performing a challenging activity. Vicarious experiences involve watching someone successfully perform the activity. Verbal persuasion involves adults providing evidence to youth about their ability to perform a challenging activity. Anxiety management involves learning how to manage one's fears about performing a challenging activity. An example of how counselors can incorporate these four sources of self-efficacy into school and community settings is the Career Horizons program developed by O'Brien and her colleagues. As part of the Career Horizons curriculum, a scientist from the community provides an encouraging talk about why girls should consider science careers, and then participates with the girls in a challenging science task. The girls not only receive verbal persuasion, but also the fun activity reduces anxiety and provides both vicarious and mastery experiences.

Additional ingredients that promote the creation of optimal learning environments have been identified by Brown and Ryan Krane's 2000 meta-analysis of career intervention literature. In addition to vicarious feedback, their meta-analysis indicated that curricula involving written exercises, individualized interpretations and feedback, information about the world of work, and guidance on building support networks were found to have a better impact on influencing career development. Curricula that contained multiple ingredients showed stronger outcomes. Howard and Solberg's Achieving Success Identities Pathways Program is one example of a counseling-oriented program creating optimal learning conditions within classroom settings. The program provides youth with individualized work readiness feedback related to academic self-efficacy, motivation, stress and health; includes discussions connecting school success to work success; explores the range and function of informal and formal support systems; and uses written exercises throughout.

In conclusion, SCANS offers an outline of work readiness skills and dispositions necessary to successfully enter the world of work. Integrating research from self-determination theory, social cognitive theory, and Brown and Ryan Krane offers nine ingredients of optimal learning environments that can promote the development of these work readiness skills and dispositions. These ingredients are written exercises, individualized interpretations and feedback, world of work information, modeling opportunities, attention to building support for choices within one's social network, mastery experiences, anxiety management skills, and opportunities for establishing stronger relational connections between youth and their teachers.

## WORK–FAMILY BALANCE

---

Balancing the demands and domains of work and family life presents major challenges for individuals, couples, and families. Career counselors and all counseling professionals must be able to comprehend and assist people to deal with issues of work–family balance. This entry considers work–family balance from the perspectives of history and career intervention.

### History

The relationship between the domains of work and family has undergone many shifts in the United States. Prior to the Industrial Revolution, families tended to work together, usually where they lived (farms, small businesses), in sustainable ways. Although men's and women's roles within those families differed (men engaged in manual labor and trade; women were in charge of sustenance, family needs, and domestic tasks), all of the duties were seen as of equal necessity and importance. Further, the education and care of children was equally divided, as children accompanied their same-sex parent in the performance of work. At this point in history, childhood was short: children became "little adults" as soon as they were able.

The Industrial Revolution and the accompanying geographic shift of work from home to cities resulted in a separation of those two domains. Sustainability was now segregated into two separate spheres and gender-specific roles. Shortly thereafter the ideology of

separate spheres emerged: men's sphere was public and regulated, while the domain of women remained private and unregulated. Men governed the family, social and political institutions, and the economy, while women managed the home, emotions, culture, morality, and children. This doctrine of separate spheres remained dominant until quite recently. Further, ideas about the ideal mother (careworker), ideal father (breadwinner), and the ideal worker (an employee primarily dedicated to his paid job) proliferated.

During and after World War I, women began to express interest in personal satisfaction, and ambition, but their participation in the labor force did not increase until the Great Depression and World War II. Nevertheless, the right of the married woman to work was debated vociferously and was a tenet of early feminism. Ultimately, because of the draft and the war, women were needed to work in factories and businesses. The image of Rosie the Riveter was a patriotically inspiring image, new dignity was conferred on women's wage work, and women liked going to work. Their wage work acquired unprecedented public prominence and contributed significantly to the economy. After World War II, men reclaimed their manufacturing jobs, and women's labor participation reached its lowest level of the century. Women were strongly encouraged to return home, and the passage of the Fair Labor Standards Act of 1938 and the Family Wage Act of 1939 plus the enticement of home ownership and the new domestic labor-saving devices facilitated that choice. Men's earning power grew, and women's work was discouraged. Women's experience at work during the war, however, had altered women's attitudes about work considerably, and even though the economic upturn during the 1950s resulted in the ability of many men to support their families on one income, women were attracted to the labor market. During the last quarter of the 20th century, a number of forces coalesced to change women's labor force participation: (1) increasing access to higher education for women; (2) the Women's Movement, which successfully advocated for equal opportunity for women in the workplace; (3) the introduction of birth control; (4) the increase in the age of marriage; (5) the decrease in the fertility rate; (6) the increasing divorce rate; (7) the steady decline in the earning power of men's wages; and (8) an increase in Americans' material expectations. By the 1960s, the traditional breadwinner-homemaker

lifestyle began to give way to the current normative pattern: the dual-earner couple, in which both members work for pay. Today, more than half of all married couples both work, as do 66.5% (as of 2005) of all parents, and 57% of couples with children under the age of 6. Further, the average amount of time that couples spend at work has increased dramatically (by about 10 hours a week) in the last 20 years.

This new dual-earner arrangement has created both new problems and new opportunities for families, and for the workplace. Working couples are vulnerable to role conflict, work-family spillover, and the problem of "three jobs, two people." Further, the United States lags behind most other developed countries in the provision of state-supported child care and paid leave.

At the same time, working couples often have slightly more disposable income, and both generations X and Y are more egalitarian in their attitudes toward child rearing and child care, challenging the idea of the ideal worker. This shift in attitudes is beginning to pose a problem for some industries, such as law and finance. Turnover among midcareer professionals was growing; this is costly for firms, who estimate that the replacement costs of employees is more than 30% of individuals' salary. This bottom-line impact is of concern to companies, and since around 1980, companies with many employees have both studied work-family issues and implemented policies to address them. And the multidisciplinary study of work-family is increasing dramatically. Since 1977, the year that Rosabeth Moss Kanter published her monograph on work and family, scholarly work has burgeoned. More than 3,500 articles were published in 2000, but few of them have been cited by clinicians in their work.

## Implications for Counseling

### *Ideological Expectations*

The ideological model of intensive mothering among White families began to emerge in the 1930s and pervaded through the 1970s. This model was informed by the changing beliefs about child rearing, the emergence of psychological (Freud, Erikson) and cognitive (Jean Piaget) developmental models, and the increase in availability of mothering "experts" such as Benjamin Spock. Although more women are working, and more women are working full-time,

full-year, this set of beliefs has not changed much, and can result in considerable conflict and guilt for both men and women.

### ***Role Conflict***

Research suggests that despite the increase in egalitarian beliefs among men and women in marriage, traditional gender roles, especially reflected in the division of labor at home, remain powerfully ingrained. The psychological tension embedded in the conflict between work and family roles has been described as occurring bidirectionally: either from work to family or family to work. From a research perspective, they are distinct reciprocal constructs with independent antecedents and outcomes. Further, there is evidence to suggest that the relationship between work–family conflict and job satisfaction is decidedly negative. These conflicts can be time-based (e.g., needing to work late), strain-based (anxiety about a child's illness might interfere with the ability to concentrate at work), or behavior-based (conflict stemming from incompatible behaviors demanded by competing roles, e.g., being appropriately aggressive and unemotional in a specific work role such as litigator is probably not appropriate at home). Further, despite increasing egalitarianism, the burden of care-work continues to fall mostly on women. Nearly 80% (79.9%) of women report having the main or total responsibility for child care in their households, and this statistic does not include caring for ill or aging relatives. Data suggest that even when men participate in domestic work and child care, they tend to choose what they do and the executive function in the household tends to be located in women. This is not to say that men are not involved at home nor is it suggested that men do not experience work–family conflict. From a practice perspective, both kinds of conflict can have implications for male and female clients. Since identity is often embedded in social role, these kinds of conflicts can be quite disturbing to clients. From a couples' perspective, work–family conflict is often associated with differing gender-role expectations rather than with the role demands themselves, that is, the degree to which their gender-role expectations differ and the degree to which their individual work and family roles are ego-dystonic. Because role expectations are so deeply embedded, they can be difficult to discuss for both individuals and couples.

The opposite of work–family conflict is work-to-family facilitation, positively associated with job- and

life-satisfaction, negatively with stress and family-to-work facilitation, positively associated with marital- and family-satisfaction, and negatively associated with organizational commitment. But working mothers report more work–family conflict and stress and less family-, marital-, and life-satisfaction than working fathers.

### ***Role Overload***

Not the same as role conflict, role overload refers to the sheer number of role demands. There is some evidence to suggest that parenting is less effective when role overload occurs in the work domain, but too much work is not in and of itself negative. Rather, schedule fit and control are better predictors of psychological distress.

### ***Spillover***

Multiple role occupancy is, in itself, not necessarily detrimental to individuals. Chait Barnett and Shibley Hyde have suggested that multiple roles are generally beneficial for both men and women, and have positive implications for psychological well-being. This is known as either positive spillover or work–family enrichment.

### ***Work Schedules and Family-Friendly Policies***

Until quite recently, work schedules were, for the most part, rigid, resulting in considerable stress for working parents. In the last 20 years, employers in the United States have demanded more and more time on the job. This is especially true for the service sector. Accountants, lawyers, and finance professionals, for example, are expected to be client-friendly 24 hours a day, 7 days a week. Despite this 24/7 expectation, many employers have recently seen the bottom-line benefit of flexible schedules: reduced turnover, reduced absenteeism, higher organizational commitment, increased productivity, and higher profits. Further, it has become clear that schedule flexibility (the agile workplace) is the single best family-friendly benefit for individuals as well as for organizations. Other family-friendly policies include family medical leave benefits, paid leave, telecommuting, on-site child care, aging and child care resources, and referral services, to name a few. Family-supportive policies seem to be associated with reduced work–family conflict. The question of utilization, however, remains a problem.

The existence of good policies is not necessarily career neutral. There is some evidence to suggest that in firms that value highly driven employees, taking advantage of such policies can derail individuals. *Working Mother Magazine* lists the 100 best companies to work for based on both the existence of formal policies and their utilization. For the individual experiencing conflict, however, the absence of good problem-focused coping strategies and proactivity can result in increased stress. It has been found that stressed individuals who use problem-focused coping exhibit less strain than those who do not, but that emotion-focused coping strategies do not lead to positive outcomes. Research also suggests that the use of informal work accommodations to family can be more effective than rigid work-family organizational policies.

### **Child Care**

The satisfactoriness of child care is directly related to income: the higher one's income, the more likely one is to be able not only to afford child care, but also to have choices about whether that care is delivered at home or in day care. Although for the most part, research has focused on child care for young children, the issue of afterschool care is gaining increased prominence. It is worthwhile to note that the United States is one of the few developed countries whose government does not subsidize some form of child care.

### **Child Outcomes**

The potentially negative effect of maternal employment on children has been studied longer than any other work-family issue. It appears that when mothers engage in paid employment for more than 30 hours per week while their children are younger than 9 months, negative effects on some aspects of cognitive and social development are found. Some of those effects may persist into the school-age years. These data, however, are not universal and are influenced by child gender, ethnicity, child care quality, home environment quality, maternal sensitivity, and socioeconomic status. The equality of the marital relationship appears to be critical to positive child outcomes.

### **Stress and Illness**

Much of the research on stress and illness appears under the rubric of health psychology. Substance abuse has been studied in this domain, as has stress.

The interactions between work and family can provide multiple potential stressors, which in turn can be associated with depression, anxiety, burnout, and role overload. In addition, recent research suggests that parental concern over what children are doing after school is a major source of employee stress. Working mothers lose approximately one night's worth of sleep a week, due to the combined demands of work and family. Husbands whose wives work 40 or more hours a week experience poorer health than do husbands whose wives work shorter hours. Finally, it is important to mention that working nonstandard hours exacerbates almost all work-family difficulties. These findings tend to be associated with low-wage workers and are not independent of ethnicity and socioeconomic status.

### **Off- and On-Ramping**

The U.S. economy incurs a significant loss of human capital in that many highly educated, middle-class mothers leave the workforce (i.e., opt out) because they cannot get career continuous part-time arrangements. How women manage their careers once they have children has been the subject of much interest, but of less research. Sylvia Hewlett and Carolyn Luce found that 37% of women voluntarily leave their careers at some point and that 43% of women who have children do so. Caring for elderly parents also pulls women out of the labor force. But, the "pulls" of children and health are not the only triggers. The "push" of lack of opportunity or understimulation are also proximate causes. For the most part, these women have every intention of returning to the labor force, but they pay a high cost for time out, both financially (a loss of an average of 18% of their salaries, a loss of 37% if they stay out for 3 years) and in terms of career trajectory. Because prime childbearing years coincide with prime career-building years in almost every occupation, the penalty for using alternative work arrangements or for stepping out even briefly can be steep. As corporate employers begin to recognize this brain drain, however, they are funding experimental reentry programs at law and business schools to try to ameliorate the loss to both individuals and industry.

### **Clinical Interventions**

The interface between work and family is an important topic for counseling. Although much of the research cited here is about White, middle-class, heterosexual two-parent families, there is an

increasing body of knowledge about low-wage workers, single parents, lesbian families, and families of color. Further, the research on work and family issues cross-nationally can also inform, especially when one looks at the effects of national policy differences. And, the absence of literature on the relationship between work–family and clinical interventions is notable. Despite the fact that caseloads increasingly include individuals and couples who are struggling with the issue of balancing work and family, little guidance is available for the counselor or therapist. Kelli A. Saginak and M. Alan Saginak recommend giving high priority to helping couples create marital equality and an equitable distribution of labor, while Ada Sinacore-Guinn and colleagues remind counselors to explore family environment when women enter or reenter the labor force, when clients voice job dissatisfaction, and as they engage in family planning. Finally, when engaging in individual or couples counseling when work–family issues are central, there are two foci: the two individuals' career or job voices and how those voices are associated with the home environment.

## WORK STRESS

---

Work now more than ever consumes large portions of people's lives. The importance of work in people's lives, alongside the demands on one's time and energy, can be a tremendous source of stress. Increases in work stress may result from people having longer work hours, threats of job loss due to organization downsizing, or a host of other factors, such as the day-to-day strains in the work environment. Aspects of one's personal life can make dealing with stress at work even more difficult. Although many sources of stress are apparent in everyday life, most people would probably report at least some level of stress at work. In some cases, work stress can be the number one source of stress in people's lives. Work stress can result from a lack of control over work, which can leave a person feeling undervalued and underappreciated, or it can be due to particular issues in the workplace environment, such as shift work, long work hours, time pressures, noise, surveillance and monitoring, and working with hazardous products. Interpersonal conflicts with coworkers and supervisors can also contribute to increases in work stress.

Work stress is perceived and interpreted differently by individuals, and people will cope and respond to stress in different ways. Situations that may impose stress on one individual may not be stressful to others. Individual characteristics such as personality traits and coping style can influence how a person responds to work stress. Although these characteristics can be partly responsible for how people respond to stress, working conditions such as workload demands and pressures, conflicting expectations, or fear of layoffs or being fired can influence the amount of stress that one feels. Individuals with certain personality characteristics, such as type A personality traits or people prone to depression, may respond more often and more intensely to work-related stress. Work stress can also result from an imbalance between a person's

efforts and the personal rewards he or she receives from work: for example, workers who take on responsibilities above and beyond their normal workload but who do not receive the promotion they felt they deserved.

Work stress can depend on a person's developmental stage of life, with sources of work stress being different for a new high school graduate compared to a worker in his or her 60s. Demographic and personal factors can also be associated with work stress and include age, gender, race and ethnic differences, financial problems, family issues (i.e., caring for children or aged parents, dual-career couples). Work stress can result from a poor fit between the worker and the environment. Poor person-environment fit can lead to psychosocial stresses and strains that adversely affect the worker. A poor fit between the person and work environment can be longstanding or brought on by recent changes in the work environment, such as requiring workers to learn new forms of technology (i.e., computers).

### **Importance of Work in People's Lives**

The importance of work in people's lives cannot be underestimated, and work means different things to different people. For some individuals work provides an income and is essentially a means to survive, whereas for others it gives purpose to their lives and is a means to express or fulfill their interests. Some people use work as a means to occupy their time, and there are other individuals for whom work provides self-respect, a sense of identity, and feelings of pride. It is not uncommon to find individuals who live to work, while other people work to live. Both perspectives on the meaning of work in people's lives can be associated with work stress. For example, for individuals who live to work, their identity may be closely tied to work. They may work long hours in order to succeed and be promoted and, therefore, be more regularly exposed to stress-producing aspects of the work environment. For individuals who work to live, fear of losing their job, and therefore their income, may significantly contribute to work stress.

### **Work Stress and Health**

While there may be some benefits to small amounts of stress, such as helping one to remain productive and challenged at work, prolonged stress can have debilitating consequences. Despite work posing an

exciting challenge for people, it can significantly contribute to health problems that include both physical and psychological symptoms. Although work stress is not a disease, work stress is a negative health outcome. Work stress can lead to health problems, including the onset of new health concerns such as cardiovascular disease or it can exacerbate existing conditions such as asthma, irritable bowel syndrome, or high blood pressure. Mood and sleep disturbances, headaches, fatigue, chronic pain, and gastrointestinal problems can be associated with work stress. Depression and anxiety can also be linked to prolonged work stress. These health concerns can lead to increased absenteeism, decreased work performance, and increased health insurance expenditures. Most concerning is the relationship between work stress and behavioral problems, such as anger that can lead to violence in or out of the workplace. Work stress can also contribute to alcohol or other drug abuse, whereby people use alcohol and other drugs to regulate their emotions and cope with difficult and stressful work situations. Increased caffeine consumption and smoking may also result from work stress.

### **Coping With Work Stress**

Given that stress in the workplace may be common and, at times, unavoidable, helping employees cope with stress is an important task for employers. Employee Assistance Programs, known as EAPs, can often serve as a first line of defense for people experiencing unmanageable work-related stress. EAPs may offer different types of educational programs to help employees cope with work stress. EAPs often offer stress management programs, which may help employees learn how to identify forms of stress in their lives; learn relaxation, time management, and coping strategies; and become aware of the effects of stress on health. EAPs also typically offer individual counseling, which can help people with personal skills reduce work stress. Personal counseling is also available to employees whose home life or personal life contributes to work stress. Counselors may help the individual cope, for example, by figuring out ways to reduce work environment conflict or to balance work and family and personal life. A counselor's role may also be to help the individual develop and utilize a supportive network of friends and family and coworkers. Additionally, finding ways to use leisure to cope with work stress may also be helpful. Leisure

time may be especially helpful in decreasing depression and anxiety brought on by work stress.

Work stress can lead to job dissatisfaction and employee turnover as well as to burnout, which is caused by a prolonged imbalance between work and the individual. Coping with stress can hopefully prevent burnout. Individuals who feel that they work in a supportive atmosphere and who feel that their work provides them with challenges are at lesser risk for burnout. Individuals who have strong interpersonal qualities and social supports may be less likely to develop burnout. Developing a person's inner set of strengths through counseling may help to ward off burnout, build resiliency, and help work to be perceived as more satisfying and less stressful. Prevention and intervention strategies should be geared toward the individual.

### Measuring Work Stress

In order to assist individuals with devising coping and intervention strategies to manage work-related stress, it may be helpful to formally assess levels of occupational stress. A tool that can be used to comprehensively measure work-related stress is the Occupational Stress Inventory-Revised Edition (OSI-R). It consists of three questionnaires comprising 140 items (total) designed to measure three domains of occupational adjustment: occupational stress, psychological strain, and coping resources. The OSI-R can be completed in 30 minutes and provides information about the domains using 14 scales. The results can be used to help individuals understand sources of their occupational stress, work roles that contribute to their stress, and outcome information about coping strategies and interventions.

## WORK VALUES

It is generally accepted that there are three or four things that contribute to success and satisfaction at work or in a career. Skills or abilities are foundations of success; interests and work values are the sources of satisfaction. Skills and abilities and interests are generally understood by people seeking jobs; work values are less well understood.

Generally work values have been defined in terms of preferences for jobs, occupations, or careers. Work values differ from interests, which are preferences for activities, such as science, helping others, or selling things. Work values vary from one person to another even in the same job: One person may like a job because it pays well; another may like the same job because it affords many social relationships.

Many work values have been named, and Donald Super has classified them into three categories: the results of work, such as high pay; the concomitants of work, such as the people one works with; and the nature of the work itself, such as challenging assignments. These job characteristics are typically termed as positive attributes. Negative attributes, such as danger, are not valued, but in an occupation like firefighting where danger is inevitable, it is reframed as challenge.

Super's Work Values Inventory-Revised is a popular measure of work values. It was first formulated by Super in the 1950s and published for general use in the 1970s. A revision is now available from Kuder, Inc., that assesses 12 work values using 12 scales: Achievement, Challenge, Co-Workers, Creativity,

Income, Independence, Lifestyle, Prestige, Security, Supervision, Variety, and Workplace. Other measures of work values include additional concepts measured on scales such as Moral Values and Physical Activity. Each scale consists of four statements about jobs, such as “A job in which I work with people I like,” and “. . . have coworkers who are easy to work with” (Co-Workers scale). Responses are made on a 5-point scale from *not important at all* to *crucial*. Percentile scores are used to rank order the importance of the work values. Interpretation is in the form of, “You describe yourself as valuing prestige, creativity, and variety most in a job.”

Some conceptualizations of work values indicate that occupations are homogeneous with respect to work values. That is, one may name a work value and identify all the occupations that are responsive to that value. Super’s Work Values Inventory endorses the concept that the variety of jobs within an occupation may satisfy different values. For instance, an engineer might be self-employed in consulting work because he or she values independence, while another might be employed in a research and development position because he or she values creativity. In its application in the Kuder Career Planning System, Super’s Work Values Inventory users may open several job interviews

that illustrate each work value in the context of a job. For instance, a probation–parole officer for adult offenders values “the capacity to make ninety-five percent of my decisions without approval from others; a realistic statement of Independence” (Super, 1995).
